FIELD OF THE INVENTION

The invention relates generally to phosphonate containing compounds with antiviral activity.

BACKGROUND OF THE INVENTION

5 Improving the delivery of drugs and other agents to target cells and tissues has been the focus of considerable research for many years. Though many attempts have been made to develop effective methods for importing biologically active molecules into cells, both *in vivo* and *in vitro*, none has proved to be entirely satisfactory. Optimizing the association of the inhibitory
10 drug with its intracellular target, while minimizing intercellular redistribution of the drug, *e.g.*, to neighboring cells, is often difficult or inefficient.

Most agents currently administered to a patient parenterally are not targeted, resulting in systemic delivery of the agent to cells and tissues of the body where it is unnecessary, and often undesirable. This may result in adverse
15 drug side effects, and often limits the dose of a drug (*e.g.*, glucocorticoids and other anti-inflammatory drugs) that can be administered. By comparison, although oral administration of drugs is generally recognized as a convenient and economical method of administration, oral administration can result in either (a) uptake of the drug through the cellular and tissue barriers, *e.g.*, blood/brain,
20 epithelial, cell membrane, resulting in undesirable systemic distribution, or (b) temporary residence of the drug within the gastrointestinal tract. Accordingly, a major goal has been to develop methods for specifically targeting agents to cells and tissues. Benefits of such treatment includes avoiding the general physiological effects of inappropriate delivery of such agents to other cells and
25 tissues, such as uninfected cells.

Thus, there is a need for therapeutic antiviral agents with improved pharmacological properties, *e.g.*, drugs having improved antiviral activity and pharmacokinetic properties, including improved oral bioavailability, greater potency and extended effective half-life *in vivo*.

30 New antiviral compounds should have fewer side effects, less complicated dosing schedules, and be orally active. In particular, there is a need for a less onerous dosage regimen, such as one pill, once per day.

Assay methods capable of determining the presence, absence or amounts of viral inhibition are of practical utility in the search for antiviral as well as for diagnosing the presence of conditions associated infection.

SUMMARY OF THE INVENTION

5 Intracellular targeting may be achieved by methods and compositions that allow accumulation or retention of biologically active agents inside cells. The present invention provides novel phosphonate analogs of antiviral compounds. These analogs possess all the utilities of the parent compounds and optionally provide cellular accumulation as set forth below.

10 In one aspect, the present invention provides novel compounds with activity against infectious viruses. The compounds of the invention may inhibit viral RNA polymerases such as, but not limited to hepatitis B, hepatitis C, Polio, Coxsackie A and B, Rhino, Echo, small pox, Ebola, and West Nile virus polymerases. The compounds of the invention may inhibit retroviral RNA
15 dependent RNA polymerases or reverse transcriptases and thus inhibit the replication of the virus. The compounds of the invention may be useful for treating human patients infected with a human retrovirus, such as hepatitis C.

20 The present invention relates generally to the accumulation or retention of therapeutic compounds inside cells. More particularly, the invention relates to attaining high concentrations of active metabolite molecules in virally infected cells (e.g. cells infected with HCV or HIV). Such effective targeting may be applicable to a variety of therapeutic formulations and procedures.

25 Accordingly, in one embodiment the invention provides a conjugate comprising an antiviral compound linked to one or more phosphonate groups; or a pharmaceutically acceptable salt or solvate thereof.

 In another embodiment, the invention provides a compound of any one of formulae 501-561:

10 DETAILED DESCRIPTION OF EXEMPLARY CLAIMS

Reference will now be made in detail to certain claims of the invention, examples of which are illustrated in the accompanying structures and formulas. While the invention will be described in conjunction with the enumerated claims, it will be understood that they are not intended to limit the invention to those claims. On the contrary, the invention is intended to cover all alternatives, modifications, and equivalents, which may be included within the scope of the present invention as defined by the claims.

DEFINITIONS

Unless stated otherwise, the following terms and phrases as used herein are intended to have the following meanings:

When tradenames are used herein, applicants intend to independently include the tradename product and the active pharmaceutical ingredient(s) of the tradename product.

"Bioavailability" is the degree to which the pharmaceutically active agent becomes available to the target tissue after the agent's introduction into the body. Enhancement of the bioavailability of a pharmaceutically active agent can provide a more efficient and effective treatment for patients because, for a given dose, more of the pharmaceutically active agent will be available at the targeted tissue sites.

The terms "phosphonate" and "phosphonate group" include functional groups or moieties within a molecule that comprises a phosphorous that is 1)

single-bonded to a carbon, 2) double-bonded to a heteroatom, 3) single-bonded to a heteroatom, and 4) single-bonded to another heteroatom, wherein each heteroatom can be the same or different. The terms "phosphonate" and "phosphonate group" also include functional groups or moieties that comprise a phosphorous in the same oxidation state as the phosphorous described above, as well as functional groups or moieties that comprise a prodrug moiety that can separate from a compound so that the compound retains a phosphorous having the characteristics described above. For example, the terms "phosphonate" and "phosphonate group" include phosphonic acid, phosphonic monoester, phosphonic diester, phosphoramidate, and phosphonothioate functional groups. In one specific embodiment of the invention, the terms "phosphonate" and "phosphonate group" include functional groups or moieties within a molecule that comprises a phosphorous that is 1) single-bonded to a carbon, 2) double-bonded to an oxygen, 3) single-bonded to an oxygen, and 4) single-bonded to another oxygen, as well as functional groups or moieties that comprise a prodrug moiety that can separate from a compound so that the compound retains a phosphorous having such characteristics. In another specific embodiment of the invention, the terms "phosphonate" and "phosphonate group" include functional groups or moieties within a molecule that comprises a phosphorous that is 1) single-bonded to a carbon, 2) double-bonded to an oxygen, 3) single-bonded to an oxygen or nitrogen, and 4) single-bonded to another oxygen or nitrogen, as well as functional groups or moieties that comprise a prodrug moiety that can separate from a compound so that the compound retains a phosphorous having such characteristics.

The term "prodrug" as used herein refers to any compound that when administered to a biological system generates the drug substance, *i.e.* active ingredient, as a result of spontaneous chemical reaction(s), enzyme catalyzed chemical reaction(s), photolysis, and/or metabolic chemical reaction(s). A prodrug is thus a covalently modified analog or latent form of a therapeutically-active compound.

"Prodrug moiety" refers to a labile functional group which separates from the active inhibitory compound during metabolism, systemically, inside a cell, by

hydrolysis, enzymatic cleavage, or by some other process (Bundgaard, Hans, "Design and Application of Prodrugs" in A Textbook of Drug Design and Development (1991), P. Krogsgaard-Larsen and H. Bundgaard, Eds. Harwood Academic Publishers, pp. 113-191). Enzymes which are capable of an
5 enzymatic activation mechanism with the phosphonate prodrug compounds of the invention include, but are not limited to, amidases, esterases, microbial enzymes, phospholipases, cholinesterases, and phosphatases. Prodrug moieties can serve to enhance solubility, absorption and lipophilicity to optimize drug delivery, bioavailability and efficacy. A prodrug moiety may include an active
10 metabolite or drug itself.

Exemplary prodrug moieties include the hydrolytically sensitive or labile acyloxymethyl esters $-\text{CH}_2\text{OC}(=\text{O})\text{R}^9$ and acyloxymethyl carbonates $-\text{CH}_2\text{OC}(=\text{O})\text{OR}^9$ where R^9 is C_1 - C_6 alkyl, C_1 - C_6 substituted alkyl, C_6 - C_{20} aryl or C_6 - C_{20} substituted aryl. The acyloxyalkyl ester was first used as a prodrug
15 strategy for carboxylic acids and then applied to phosphates and phosphonates by Farquhar et al. (1983) *J. Pharm. Sci.* 72: 324; also US Patent Nos. 4816570, 4968788, 5663159 and 5792756. Subsequently, the acyloxyalkyl ester was used to deliver phosphonic acids across cell membranes and to enhance oral bioavailability. A close variant of the acyloxyalkyl ester, the
20 alkoxycarbonyloxyalkyl ester (carbonate), may also enhance oral bioavailability as a prodrug moiety in the compounds of the combinations of the invention. An exemplary acyloxymethyl ester is pivaloyloxymethoxy, (POM) $-\text{CH}_2\text{OC}(=\text{O})\text{C}(\text{CH}_3)_3$. An exemplary acyloxymethyl carbonate prodrug moiety is pivaloyloxymethylcarbonate (POC) $-\text{CH}_2\text{OC}(=\text{O})\text{OC}(\text{CH}_3)_3$.

25 The phosphonate group may be a phosphonate prodrug moiety. The prodrug moiety may be sensitive to hydrolysis, such as, but not limited to a pivaloyloxymethyl carbonate (POC) or POM group. Alternatively, the prodrug moiety may be sensitive to enzymatic potentiated cleavage, such as a lactate ester or a phosphoramidate-ester group.

30 Aryl esters of phosphorus groups, especially phenyl esters, are reported to enhance oral bioavailability (De Lombaert et al. (1994) *J. Med. Chem.* 37: 498). Phenyl esters containing a carboxylic ester ortho to the phosphate have

also been described (Khamnei and Torrence, (1996) *J. Med. Chem.* 39:4109-4115). Benzyl esters are reported to generate the parent phosphonic acid. In some cases, substituents at the *ortho*-or *para*-position may accelerate the hydrolysis. Benzyl analogs with an acylated phenol or an alkylated phenol may generate the phenolic compound through the action of enzymes, *e.g.*, esterases, oxidases, etc., which in turn undergoes cleavage at the benzylic C-O bond to generate the phosphoric acid and the quinone methide intermediate. Examples of this class of prodrugs are described by Mitchell et al. (1992) *J. Chem. Soc. Perkin Trans. II* 2345; Glazier WO 91/19721. Still other benzylic prodrugs have been described containing a carboxylic ester-containing group attached to the benzylic methylene (Glazier WO 91/19721). Thio-containing prodrugs are reported to be useful for the intracellular delivery of phosphonate drugs. These proesters contain an ethylthio group in which the thiol group is either esterified with an acyl group or combined with another thiol group to form a disulfide. Deesterification or reduction of the disulfide generates the free thio intermediate which subsequently breaks down to the phosphoric acid and episulfide (Puech et al. (1993) *Antiviral Res.*, 22: 155-174; Benzaria et al. (1996) *J. Med. Chem.* 39: 4958). Cyclic phosphonate esters have also been described as prodrugs of phosphorus-containing compounds (Erion et al., US Patent No. 6312662).

“Protecting group” refers to a moiety of a compound that masks or alters the properties of a functional group or the properties of the compound as a whole. Chemical protecting groups and strategies for protection/deprotection are well known in the art. *See e.g.*, Protective Groups in Organic Chemistry, Theodora W. Greene, John Wiley & Sons, Inc., New York, 1991. Protecting groups are often utilized to mask the reactivity of certain functional groups, to assist in the efficiency of desired chemical reactions, *e.g.*, making and breaking chemical bonds in an ordered and planned fashion. Protection of functional groups of a compound alters other physical properties besides the reactivity of the protected functional group, such as the polarity, lipophilicity (hydrophobicity), and other properties which can be measured by common analytical tools. Chemically protected intermediates may themselves be biologically active or inactive.

Protected compounds may also exhibit altered, and in some cases, optimized properties *in vitro* and *in vivo*, such as passage through cellular membranes and resistance to enzymatic degradation or sequestration. In this role, protected compounds with intended therapeutic effects may be referred to
5 as prodrugs. Another function of a protecting group is to convert the parental drug into a prodrug, whereby the parental drug is released upon conversion of the prodrug *in vivo*. Because active prodrugs may be absorbed more effectively than the parental drug, prodrugs may possess greater potency *in vivo* than the parental drug. Protecting groups are removed either *in vitro*, in the instance of
10 chemical intermediates, or *in vivo*, in the case of prodrugs. With chemical intermediates, it is not particularly important that the resulting products after deprotection, *e.g.*, alcohols, be physiologically acceptable, although in general it is more desirable if the products are pharmacologically innocuous.

Any reference to any of the compounds of the invention also includes a
15 reference to a physiologically acceptable salt thereof. Examples of physiologically acceptable salts of the compounds of the invention include salts derived from an appropriate base, such as an alkali metal (for example, sodium), an alkaline earth (for example, magnesium), ammonium and NX_4^+ (wherein X is C_1-C_4 alkyl). Physiologically acceptable salts of an hydrogen atom or an amino
20 group include salts of organic carboxylic acids such as acetic, benzoic, lactic, fumaric, tartaric, maleic, malonic, malic, isethionic, lactobionic and succinic acids; organic sulfonic acids, such as methanesulfonic, ethanesulfonic, benzenesulfonic and p-toluenesulfonic acids; and inorganic acids, such as hydrochloric, sulfuric, phosphoric and sulfamic acids. Physiologically
25 acceptable salts of a compound of an hydroxy group include the anion of said compound in combination with a suitable cation such as Na^+ and NX_4^+ (wherein X is independently selected from H or a C_1-C_4 alkyl group).

For therapeutic use, salts of active ingredients of the compounds of the invention will be physiologically acceptable, *i.e.* they will be salts derived from a
30 physiologically acceptable acid or base. However, salts of acids or bases which are not physiologically acceptable may also find use, for example, in the preparation or purification of a physiologically acceptable compound. All salts,

whether or not derived from a physiologically acceptable acid or base, are within the scope of the present invention.

25 "Carbocycle" refers to a saturated, unsaturated or aromatic ring having 3 to 7 carbon atoms as a monocycle, 7 to 12 carbon atoms as a bicycle, and up to about 20 carbon atoms as a polycycle. Monocyclic carbocycles have 3 to 6 ring atoms, still more typically 5 or 6 ring atoms. Bicyclic carbocycles have 7 to 12 ring atoms, e.g., arranged as a bicyclo [4,5], [5,5], [5,6] or [6,6] system, or 9 or
 30 10 ring atoms arranged as a bicyclo [5,6] or [6,6] system. Examples of

monocyclic carbocycles include cyclopropyl, cyclobutyl, cyclopentyl, 1-cyclopent-1-enyl, 1-cyclopent-2-enyl, 1-cyclopent-3-enyl, cyclohexyl, 1-cyclohex-1-enyl, 1-cyclohex-2-enyl, 1-cyclohex-3-enyl, phenyl, spiryl and naphthyl.

5 “Linker” or “link” refers to a chemical moiety comprising a covalent bond or a chain or group of atoms that covalently attaches a phosphonate group to a drug. Linkers include portions of substituents A¹ and A³, which include moieties such as: repeating units of alkyloxy (*e.g.*, polyethylenoxy, PEG, polymethyleneoxy) and alkylamino (*e.g.*, polyethyleneamino, Jeffamine™); and
10 diacid ester and amides including succinate, succinamide, diglycolate, malonate, and caproamide.

The term “chiral” refers to molecules which have the property of non-superimposability of the mirror image partner, while the term “achiral” refers to molecules which are superimposable on their mirror image partner.

15 The term “stereoisomers” refers to compounds which have identical chemical constitution, but differ with regard to the arrangement of the atoms or groups in space.

“Diastereomer” refers to a stereoisomer with two or more centers of chirality and whose molecules are not mirror images of one another.

20 Diastereomers have different physical properties, *e.g.*, melting points, boiling points, spectral properties, and reactivities. Mixtures of diastereomers may separate under high resolution analytical procedures such as electrophoresis and chromatography.

“Enantiomers” refer to two stereoisomers of a compound which are non-
25 superimposable mirror images of one another.

The term “treatment” or “treating,” to the extent it relates to a disease or condition includes preventing the disease or condition from occurring, inhibiting the disease or condition, eliminating the disease or condition, and/or relieving one or more symptoms of the disease or condition.

30 Stereochemical definitions and conventions used herein generally follow S. P. Parker, Ed., McGraw-Hill Dictionary of Chemical Terms (1984) McGraw-Hill Book Company, New York; and Eliel, E. and Wilen, S., Stereochemistry of

Organic Compounds (1994) John Wiley & Sons, Inc., New York. Many organic compounds exist in optically active forms, *i.e.*, they have the ability to rotate the plane of plane-polarized light. In describing an optically active compound, the prefixes D and L or R and S are used to denote the absolute configuration of the molecule about its chiral center(s). The prefixes d and l or (+) and (-) are employed to designate the sign of rotation of plane-polarized light by the compound, with (-) or l meaning that the compound is levorotatory. A compound prefixed with (+) or d is dextrorotatory. For a given chemical structure, these stereoisomers are identical except that they are mirror images of one another. A specific stereoisomer may also be referred to as an enantiomer, and a mixture of such isomers is often called an enantiomeric mixture. A 50:50 mixture of enantiomers is referred to as a racemic mixture or a racemate, which may occur where there has been no stereoselection or stereospecificity in a chemical reaction or process. The terms "racemic mixture" and "racemate" refer to an equimolar mixture of two enantiomeric species, devoid of optical activity.

Protecting Groups

In the context of the present invention, protecting groups include prodrug moieties and chemical protecting groups.

Protecting groups are available, commonly known and used, and are optionally used to prevent side reactions with the protected group during synthetic procedures, *i.e.* routes or methods to prepare the compounds of the invention. For the most part the decision as to which groups to protect, when to do so, and the nature of the chemical protecting group "PG" will be dependent upon the chemistry of the reaction to be protected against (*e.g.*, acidic, basic, oxidative, reductive or other conditions) and the intended direction of the synthesis. The PG groups do not need to be, and generally are not, the same if the compound is substituted with multiple PG. In general, PG will be used to protect functional groups such as carboxyl, hydroxyl, thio, or amino groups and to thus prevent side reactions or to otherwise facilitate the synthetic efficiency. The order of deprotection to yield free, deprotected groups is dependent upon the intended direction of the synthesis and the reaction conditions to be encountered, and may occur in any order as determined by the artisan.

Various functional groups of the compounds of the invention may be protected. For example, protecting groups for -OH groups (whether hydroxyl, carboxylic acid, phosphonic acid, or other functions) include "ether- or ester-forming groups". Ether- or ester-forming groups are capable of functioning as chemical protecting groups in the synthetic schemes set forth herein. However, some hydroxyl and thio protecting groups are neither ether- nor ester-forming groups, as will be understood by those skilled in the art, and are included with amides, discussed below.

A very large number of hydroxyl protecting groups and amide-forming groups and corresponding chemical cleavage reactions are described in Protective Groups in Organic Synthesis, Theodora W. Greene (John Wiley & Sons, Inc., New York, 1991, ISBN 0-471-62301-6) ("Greene"). See also Kocienski, Philip J.; Protecting Groups (Georg Thieme Verlag Stuttgart, New York, 1994), which is incorporated by reference in its entirety herein. In particular Chapter 1, Protecting Groups: An Overview, pages 1-20, Chapter 2, Hydroxyl Protecting Groups, pages 21-94, Chapter 3, Diol Protecting Groups, pages 95-117, Chapter 4, Carboxyl Protecting Groups, pages 118-154, Chapter 5, Carbonyl Protecting Groups, pages 155-184. For protecting groups for carboxylic acid, phosphonic acid, phosphonate, sulfonic acid and other protecting groups for acids see Greene as set forth below. Such groups include by way of example and not limitation, esters, amides, hydrazides, and the like.

Ether- and Ester-forming protecting groups

Ester-forming groups include: (1) phosphonate ester-forming groups, such as phosphoramidate esters, phosphorothioate esters, phosphonate esters, and phosphon-bis-amidates; (2) carboxyl ester-forming groups, and (3) sulphur ester-forming groups, such as sulphonate, sulfate, and sulfinat.

The phosphonate moieties of the compounds of the invention may or may not be prodrug moieties, *i.e.* they may or may be susceptible to hydrolytic or enzymatic cleavage or modification. Certain phosphonate moieties are stable under most or nearly all metabolic conditions. For example, a dialkylphosphonate, where the alkyl groups are two or more carbons, may have appreciable stability *in vivo* due to a slow rate of hydrolysis.

Within the context of phosphonate prodrug moieties, a large number of structurally-diverse prodrugs have been described for phosphonic acids (Freeman and Ross in Progress in Medicinal Chemistry 34: 112-147 (1997) and are included within the scope of the present invention. An exemplary
 5 phosphonate ester-forming group is the phenyl carbocycle in substructure A₃ having the formula:

wherein R₁ may be H or C₁-C₁₂ alkyl; m₁ is 1, 2, 3, 4, 5, 6, 7 or 8, and the phenyl carbocycle is substituted with 0 to 3 R₂ groups. Where Y₁ is O, a
 10 lactate ester is formed, and where Y₁ is N(R₂), N(OR₂) or N(N(R₂)₂), a phosphonamidate ester results.

In its ester-forming role, a protecting group typically is bound to any acidic group such as, by way of example and not limitation, a -CO₂H or -C(S)OH group, thereby resulting in -CO₂R^x where R^x is defined herein. Also,
 15 R^x for example includes the enumerated ester groups of WO 95/07920.

Examples of protecting groups include:

- chiral center is (R), (S) or racemate.

- 5 Other esters that are suitable for use herein are described in EP 632048.
Protecting groups also includes "double ester" forming profunctionalities

- such as $-\text{CH}_2\text{OC}(\text{O})\text{OCH}_3$, $-\text{CH}_2\text{SCOCH}_3$, $-\text{CH}_2\text{OCON}(\text{CH}_3)_2$, or
alkyl- or aryl-acyloxyalkyl groups of the structure $-\text{CH}(\text{R}^1 \text{ or } \text{W}^5)\text{O}((\text{CO})\text{R}^{37})$ or
 $-\text{CH}(\text{R}^1 \text{ or } \text{W}^5)((\text{CO})\text{OR}^{38})$ (linked to oxygen of the acidic group) wherein R^{37}
10 and R^{38} are alkyl, aryl, or alkylaryl groups (see U.S. Patent No. 4,968,788).
Frequently R^{37} and R^{38} are bulky groups such as branched alkyl, ortho-
substituted aryl, meta-substituted aryl, or combinations thereof, including
normal, secondary, iso- and tertiary alkyls of 1-6 carbon atoms. An example is
the pivaloyloxymethyl group. These are of particular use with prodrugs for oral
15 administration. Examples of such useful protecting groups are
alkylacyloxymethyl esters and their derivatives, including -

- $\text{CH}(\text{CH}_2\text{CH}_2\text{OCH}_3)\text{OC}(\text{O})\text{C}(\text{CH}_3)_3$,
 $\text{CH}_2\text{OC}(\text{O})\text{C}_{10}\text{H}_{15}$, $-\text{CH}_2\text{OC}(\text{O})\text{C}(\text{CH}_3)_3$, $-\text{CH}(\text{CH}_2\text{OCH}_3)\text{OC}(\text{O})\text{C}(\text{CH}_3)_3$, -
 $\text{CH}(\text{CH}(\text{CH}_3)_2)\text{OC}(\text{O})\text{C}(\text{CH}_3)_3$, $-\text{CH}_2\text{OC}(\text{O})\text{CH}_2\text{CH}(\text{CH}_3)_2$, -

 $\text{CH}_2\text{OC}(\text{O})\text{CH}_2\text{CH}_3$, $-\text{CH}_2\text{OC}(\text{O})\text{CH}(\text{CH}_3)_2$, $-\text{CH}_2\text{OC}(\text{O})\text{C}(\text{CH}_3)_3$ and -
 $\text{CH}_2\text{OC}(\text{O})\text{CH}_2\text{C}_6\text{H}_5$.

In some claims the protected acidic group is an ester of the acidic group and is the residue of a hydroxyl-containing functionality. In other claims, an amino compound is used to protect the acid functionality. The residues of suitable hydroxyl or amino-containing functionalities are set forth above or are
5 found in WO 95/07920. Of particular interest are the residues of amino acids, amino acid esters, polypeptides, or aryl alcohols. Typical amino acid, polypeptide and carboxyl-esterified amino acid residues are described on pages 11-18 and related text of WO 95/07920 as groups L1 or L2. WO 95/07920 expressly teaches the amidates of phosphonic acids, but it will be understood that
10 such amidates are formed with any of the acid groups set forth herein and the amino acid residues set forth in WO 95/07920.

Typical esters for protecting acidic functionalities are also described in WO 95/07920, again understanding that the same esters can be formed with the acidic groups herein as with the phosphonate of the '920 publication. Typical
15 ester groups are defined at least on WO 95/07920 pages 89-93 (under R³¹ or R³⁵), the table on page 105, and pages 21-23 (as R). Of particular interest are esters of unsubstituted aryl such as phenyl or arylalkyl such benzyl, or hydroxy-, halo-, alkoxy-, carboxy- and/or alkylestercarboxy-substituted aryl or alkylaryl, especially phenyl, ortho-ethoxyphenyl, or C₁-C₄ alkylestercarboxyphenyl
20 (salicylate C₁-C₁₂ alkylesters).

The protected acidic groups, particularly when using the esters or amides of WO 95/07920, are useful as prodrugs for oral administration. However, it is not essential that the acidic group be protected in order for the compounds of this invention to be effectively administered by the oral route. When the compounds
25 of the invention having protected groups, in particular amino acid amidates or substituted and unsubstituted aryl esters are administered systemically or orally they are capable of hydrolytic cleavage *in vivo* to yield the free acid.

One or more of the acidic hydroxyls are protected. If more than one acidic hydroxyl is protected then the same or a different protecting group is
30 employed, *e.g.*, the esters may be different or the same, or a mixed amidate and ester may be used.

Typical hydroxy protecting groups described in Greene (pages 14-118)

More typically, protected amino groups include carbamates and amides, still more typically, -NHC(O)R^1 or $\text{-N=CR}^1\text{N(R}^1\text{)}_2$. Another protecting group, also useful as a prodrug for amino or $\text{-NH(R}^5\text{)}$, is:

See for example Alexander, J. et al. (1996) *J. Med. Chem.* 39:480-486.

Amino acid and polypeptide protecting group and conjugates

An amino acid or polypeptide protecting group of a compound of the invention has the structure $\text{R}^{15}\text{NHCH(R}^{16}\text{)C(O)-}$, where R^{15} is H, an amino acid or polypeptide residue, or R^5 , and R^{16} is defined below.

R^{16} is lower alkyl or lower alkyl ($\text{C}_1\text{-C}_6$) substituted with amino, carboxyl, amide, carboxyl ester, hydroxyl, $\text{C}_6\text{-C}_7$ aryl, guanidinyl, imidazolyl, indolyl, sulfhydryl, sulfoxide, and/or alkylphosphate. R^{10} also is taken together with the amino acid α N to form a proline residue ($\text{R}^{10} = \text{-CH}_2\text{)}_3$). However,

R^{10} is generally the side group of a naturally-occurring amino acid such as H, -CH₃, -CH(CH₃)₂, -CH₂-CH(CH₃)₂, -CHCH₃-CH₂-CH₃, -CH₂-C₆H₅, -CH₂CH₂-S-CH₃, -CH₂OH, -CH(OH)-CH₃, -CH₂-SH, -CH₂-C₆H₄OH, -CH₂-CO-NH₂, -CH₂-CH₂-CO-NH₂, -CH₂-COOH, -CH₂-CH₂-COOH, -(CH₂)₄-NH₂ and -
 5 (CH₂)₃-NH-C(NH₂)-NH₂. R_{10} also includes 1-guanidinoprop-3-yl, benzyl, 4-hydroxybenzyl, imidazol-4-yl, indol-3-yl, methoxyphenyl and ethoxyphenyl.

Another set of protecting groups include the residue of an amino-containing compound, in particular an amino acid, a polypeptide, a protecting group, -NHSO₂R, NHC(O)R, -N(R)₂, NH₂ or -NH(R)(H), whereby for example
 10 a carboxylic acid is reacted, *i.e.* coupled, with the amine to form an amide, as in C(O)NR₂. A phosphonic acid may be reacted with the amine to form a phosphonamidate, as in -P(O)(OR)(NR₂).

In general, amino acids have the structure $R^{17}C(O)CH(R^{16})NH-$, where R^{17} is -OH, -OR, an amino acid or a polypeptide residue. Amino acids are low
 15 molecular weight compounds, on the order of less than about 1000 MW and which contain at least one amino or imino group and at least one carboxyl group. Generally the amino acids will be found in nature, *i.e.*, can be detected in biological material such as bacteria or other microbes, plants, animals or man. Suitable amino acids typically are alpha amino acids, *i.e.* compounds
 20 characterized by one amino or imino nitrogen atom separated from the carbon atom of one carboxyl group by a single substituted or unsubstituted alpha carbon atom. Of particular interest are hydrophobic residues such as mono- or di-alkyl or aryl amino acids, cycloalkylamino acids and the like. These residues contribute to cell permeability by increasing the partition coefficient of the
 25 parental drug. Typically, the residue does not contain a sulfhydryl or guanidino substituent.

Naturally-occurring amino acid residues are those residues found naturally in plants, animals or microbes, especially proteins thereof. Polypeptides most typically will be substantially composed of such naturally-
 30 occurring amino acid residues. These amino acids are glycine, alanine, valine, leucine, isoleucine, serine, threonine, cysteine, methionine, glutamic acid, aspartic acid, lysine, hydroxylysine, arginine, histidine, phenylalanine, tyrosine,

tryptophan, proline, asparagine, glutamine and hydroxyproline. Additionally, unnatural amino acids, for example, valanine, phenylglycine and homoarginine are also included. Commonly encountered amino acids that are not gene-
5 in the present invention may be either the D- or L- optical isomer. In addition, other peptidomimetics are also useful in the present invention. For a general review, see Spatola, A. F., in Chemistry and Biochemistry of Amino Acids, Peptides and Proteins, B. Weinstein, eds., Marcel Dekker, New York, p. 267 (1983).

10 When protecting groups are single amino acid residues or polypeptides they optionally are substituted at R^3 of substituents A^1 , A^2 or A^3 in a compound of the invention. These conjugates are produced by forming an amide bond between a carboxyl group of the amino acid (or C-terminal amino acid of a polypeptide for example). Similarly, conjugates are formed between R^3 and an
15 amino group of an amino acid or polypeptide. Generally, only one of any site in the parental molecule is amidated with an amino acid as described herein, although it is within the scope of this invention to introduce amino acids at more than one permitted site. Usually, a carboxyl group of R^3 is amidated with an amino acid. In general, the α -amino or α -carboxyl group of the amino acid or
20 the terminal amino or carboxyl group of a polypeptide are bonded to the parental functionalities, *i.e.*, carboxyl or amino groups in the amino acid side chains generally are not used to form the amide bonds with the parental compound (although these groups may need to be protected during synthesis of the conjugates as described further below).

25 With respect to the carboxyl-containing side chains of amino acids or polypeptides it will be understood that the carboxyl group optionally will be blocked, *e.g.*, by R^1 , esterified with R^5 or amidated. Similarly, the amino side chains R^{16} optionally will be blocked with R^1 or substituted with R^5 .

Such ester or amide bonds with side chain amino or carboxyl groups, like
30 the esters or amides with the parental molecule, optionally are hydrolyzable *in vivo* or *in vitro* under acidic (pH <3) or basic (pH >10) conditions. Alternatively, they are substantially stable in the gastrointestinal tract of humans

but are hydrolyzed enzymatically in blood or in intracellular environments. The esters or amino acid or polypeptide amidates also are useful as intermediates for the preparation of the parental molecule containing free amino or carboxyl groups. The free acid or base of the parental compound, for example, is readily
 5 formed from the esters or amino acid or polypeptide conjugates of this invention by conventional hydrolysis procedures.

When an amino acid residue contains one or more chiral centers, any of the D, L, meso, threo or erythro (as appropriate) racemates, scalemates or mixtures thereof may be used. In general, if the intermediates are to be
 10 hydrolyzed non-enzymatically (as would be the case where the amides are used as chemical intermediates for the free acids or free amines), D isomers are useful. On the other hand, L isomers are more versatile since they can be susceptible to both non-enzymatic and enzymatic hydrolysis, and are more efficiently transported by amino acid or dipeptidyl transport systems in the
 15 gastrointestinal tract.

- 10 threonine, allothreonine, phosphoserine and phosphothreonine.

- Polypeptides are polymers of amino acids in which a carboxyl group of one amino acid monomer is bonded to an amino or imino group of the next amino acid monomer by an amide bond. Polypeptides include dipeptides, low molecular weight polypeptides (about 1500-5000 MW) and proteins. Proteins
- 15 optionally contain 3, 5, 10, 50, 75, 100 or more residues, and suitably are substantially sequence-homologous with human, animal, plant or microbial proteins. They include enzymes (*e.g.*, hydrogen peroxidase) as well as immunogens such as KLH, or antibodies or proteins of any type against which one wishes to raise an immune response. The nature and identity of the
- 20 polypeptide may vary widely.

The polypeptide amides are useful as immunogens in raising antibodies against either the polypeptide (if it is not immunogenic in the animal to which it is administered) or against the epitopes on the remainder of the compound of this invention.

- 25 Antibodies capable of binding to the parental non-peptidyl compound are used to separate the parental compound from mixtures, for example in diagnosis or manufacturing of the parental compound. The conjugates of parental compound and polypeptide generally are more immunogenic than the polypeptides in closely homologous animals, and therefore make the polypeptide
- 30 more immunogenic for facilitating raising antibodies against it. Accordingly, the polypeptide or protein may not need to be immunogenic in an animal typically used to raise antibodies, *e.g.*, rabbit, mouse, horse, or rat, but the final product

conjugate should be immunogenic in at least one of such animals. The polypeptide optionally contains a peptidolytic enzyme cleavage site at the peptide bond between the first and second residues adjacent to the acidic heteroatom. Such cleavage sites are flanked by enzymatic recognition structures, *e.g.*, a particular sequence of residues recognized by a peptidolytic enzyme.

Peptidolytic enzymes for cleaving the polypeptide conjugates of this invention are well known, and in particular include carboxypeptidases. Carboxypeptidases digest polypeptides by removing C-terminal residues, and are specific in many instances for particular C-terminal sequences. Such enzymes and their substrate requirements in general are well known. For example, a dipeptide (having a given pair of residues and a free carboxyl terminus) is covalently bonded through its α -amino group to the phosphorus or carbon atoms of the compounds herein. In claims where W₁ is phosphonate it is expected that this peptide will be cleaved by the appropriate peptidolytic enzyme, leaving the carboxyl of the proximal amino acid residue to autocatalytically cleave the phosphonoamidate bond.

Tripeptide residues are also useful as protecting groups. When a
 phosphonate is to be protected, the sequence $-X^{200}\text{-pro-}X^{201}$ - (where X^{200} is any
 amino acid residue and X^{201} is an amino acid residue, a carboxyl ester of proline,
 or hydrogen) will be cleaved by luminal carboxypeptidase to yield X^{200} with a
 15 free carboxyl, which in turn is expected to autocatalytically cleave the
 phosphonoamidate bond. The carboxy group of X^{201} optionally is esterified with
 benzyl.

Dipeptide or tripeptide species can be selected on the basis of known
 transport properties and/or susceptibility to peptidases that can affect transport to
 20 intestinal mucosal or other cell types. Dipeptides and tripeptides lacking an α -
 amino group are transport substrates for the peptide transporter found in brush
 border membrane of intestinal mucosal cells (Bai, J.P.F., (1992) *Pharm Res.*
 9:969-978). Transport competent peptides can thus be used to enhance
 bioavailability of the amidate compounds. Di- or tripeptides having one or more
 25 amino acids in the D configuration are also compatible with peptide transport
 and can be utilized in the amidate compounds of this invention. Amino acids in
 the D configuration can be used to reduce the susceptibility of a di- or tripeptide
 to hydrolysis by proteases common to the brush border such as aminopeptidase
 N. In addition, di- or tripeptides alternatively are selected on the basis of their
 30 relative resistance to hydrolysis by proteases found in the lumen of the intestine.
 For example, tripeptides or polypeptides lacking asp and/or glu are poor
 substrates for aminopeptidase A, di- or tripeptides lacking amino acid residues

on the N-terminal side of hydrophobic amino acids (leu, tyr, phe, val, trp) are poor substrates for endopeptidase, and peptides lacking a pro residue at the penultimate position at a free carboxyl terminus are poor substrates for carboxypeptidase P. Similar considerations can also be applied to the selection of peptides that are either relatively resistant or relatively susceptible to hydrolysis by cytosolic, renal, hepatic, serum or other peptidases. Such poorly cleaved polypeptide amidates are immunogens or are useful for bonding to proteins in order to prepare immunogens.

20 Linking Groups and Linkers

The invention provides conjugates that comprise an antiviral compound that is linked to one or more phosphonate groups either directly (e.g. through a covalent bond) or through a linking group (i.e. a linker). The nature of the linker is not critical provided it does not interfere with the ability of the phosphonate
25 containing compound to function as a therapeutic agent. The phosphonate or the linker can be linked to the compound (e.g. a compound of Formula 501-569) at any synthetically feasible position on the compound by removing a hydrogen or any portion of the compound to provide an open valence for attachment of the phosphonate or the linker.

30 In one embodiment of the invention the linking group or linker (which can be designated "L") can include all or a portions of the group A^0 , A^1 , A^2 , or

W³ described herein.

In another embodiment of the invention the linking group or linker has a molecular weight of from about 20 daltons to about 400 daltons.

In another embodiment of the invention the linking group or linker has a
5 length of about 5 angstroms to about 300 angstroms.

In another embodiment of the invention the linking group or linker separates the DRUG and a P(=Y¹) residue by about 5 angstroms to about 200 angstroms, inclusive, in length.

In another embodiment of the invention the linking group or linker is a
10 divalent, branched or unbranched, saturated or unsaturated, hydrocarbon chain, having from 2 to 25 carbon atoms, wherein one or more (*e.g.* 1, 2, 3, or 4) of the carbon atoms is optionally replaced by (-O-), and wherein the chain is optionally substituted on carbon with one or more (*e.g.* 1, 2, 3, or 4) substituents selected from (C₁-C₆)alkoxy, (C₃-C₆)cycloalkyl, (C₁-C₆)alkanoyl, (C₁-C₆)alkanoyloxy,
15 (C₁-C₆)alkoxycarbonyl, (C₁-C₆)alkylthio, azido, cyano, nitro, halo, hydroxy, oxo (=O), carboxy, aryl, aryloxy, heteroaryl, and heteroaryloxy.

In another embodiment of the invention the linking group or linker is of the formula W-A wherein A is (C₁-C₂₄)alkyl, (C₂-C₂₄)alkenyl, (C₂-C₂₄)alkynyl, (C₃-C₈)cycloalkyl, (C₆-C₁₀)aryl or a combination thereof, wherein W is -
20 N(R)C(=O)-, -C(=O)N(R)-, -OC(=O)-, -C(=O)O-, -O-, -S-, -S(O)-, -S(O)₂-, -N(R)-, -C(=O)-, or a direct bond; wherein each R is independently H or (C₁-C₆)alkyl.

In another embodiment of the invention the linking group or linker is a divalent radical formed from a peptide.

25 In another embodiment of the invention the linking group or linker is a divalent radical formed from an amino acid.

30 poly-L-leucine, poly-L-lysine-L-phenylalanine, poly-L-lysine or poly-L-lysine-L-tyrosine.

In another embodiment of the invention the linking group or linker is of the formula $W-(CH_2)_n$ wherein, n is between about 1 and about 10; and W is -
N(R)C(=O)-, -C(=O)N(R)-, -OC(=O)-, -C(=O)O-, -O-, -S-, -S(O)-, -S(O)₂-, -
C(=O)-, -N(R)-, or a direct bond; wherein each R is independently H or (C₁-
5 C₆)alkyl.

In another embodiment of the invention the linking group or linker is methylene, ethylene, or propylene.

In another embodiment of the invention the linking group or linker is attached to the phosphonate group through a carbon atom of the linker.

10 Intracellular Targeting

The phosphonate group of the compounds of the invention may cleave *in vivo* in stages after they have reached the desired site of action, *i.e.* inside a cell. One mechanism of action inside a cell may entail a first cleavage, *e.g.* by
15 an esterase, to provide a negatively-charged "locked-in" intermediate. Cleavage of a terminal ester grouping in a compound of the invention thus affords an unstable intermediate which releases a negatively charged "locked in" intermediate.

After passage inside a cell, intracellular enzymatic cleavage or modification of the phosphonate or prodrug compound may result in an
20 intracellular accumulation of the cleaved or modified compound by a "trapping" mechanism. The cleaved or modified compound may then be "locked-in" the cell by a significant change in charge, polarity, or other physical property change which decreases the rate at which the cleaved or modified compound can exit the cell, relative to the rate at which it entered as the phosphonate prodrug. Other
25 mechanisms by which a therapeutic effect are achieved may be operative as well. Enzymes which are capable of an enzymatic activation mechanism with the phosphonate prodrug compounds of the invention include, but are not limited to, amidases, esterases, microbial enzymes, phospholipases, cholinesterases, and phosphatases.

30 In selected instances in which the drug is of the nucleoside type, such as is the case of zidovudine and numerous other antiretroviral agents, it is known that the drug is activated *in vivo* by phosphorylation. Such activation may occur

in the present system by enzymatic conversion of the "locked-in" intermediate with phosphokinase to the active phosphonate diphosphate and/or by phosphorylation of the drug itself after its release from the "locked-in" intermediate as described above. In either case, the original nucleoside-type
5 drug will be converted, via the derivatives of this invention, to the active phosphorylated species.

From the foregoing, it will be apparent that many different drugs can be derivatized in accord with the present invention. Numerous such drugs are specifically mentioned herein. However, it should be understood that the
10 discussion of drug families and their specific members for derivatization according to this invention is not intended to be exhaustive, but merely illustrative.

Typically, compounds of the invention have a molecular weight of from about 400 amu to about 10,000 amu; in a specific embodiment of the invention,
30 compounds have a molecular weight of less than about 5000 amu; in another specific embodiment of the invention, compounds have a molecular weight of less than about 2500 amu; in another specific embodiment of the invention,

compounds have a molecular weight of less than about 1000 amu; in another specific embodiment of the invention, compounds have a molecular weight of less than about 800 amu; in another specific embodiment of the invention, compounds have a molecular weight of less than about 600 amu; and in another specific embodiment of the invention, compounds have a molecular weight of less than about 600 amu and a molecular weight of greater than about 400 amu.

The compounds of the invention also typically have a logD(polarity) less than about 5. In one embodiment the invention provides compounds having a logD less than about 4; in another one embodiment the invention provides compounds having a logD less than about 3; in another one embodiment the invention provides compounds having a logD greater than about -5; in another one embodiment the invention provides compounds having a logD greater than about -3; and in another one embodiment the invention provides compounds having a logD greater than about 0 and less than about 3.

In one specific embodiment the invention provides compounds that may fall within the generic definition of the term antiviral compound but which further comprise a phosphonate group, *e.g.*, a phosphonate diester, phosphoramidate-ester prodrug, or a phosphondiamidate-ester (Jiang et al., US 2002/0173490 A1).

Selected substituents within the compounds of the invention are present to a recursive degree. In this context, "recursive substituent" means that a substituent may recite another instance of itself. Because of the recursive nature of such substituents, theoretically, a large number may be present in any given claim. For example, R^x contains a R^y substituent. R^y can be R^2 , which in turn can be R^3 . If R^3 is selected to be R^{3c} , then a second instance of R^x can be selected. One of ordinary skill in the art of medicinal chemistry understands that the total number of such substituents is reasonably limited by the desired properties of the compound intended. Such properties include, by of example and not limitation, physical properties such as molecular weight, solubility or log P, application properties such as activity against the intended target, and practical properties such as ease of synthesis.

By way of example and not limitation, W^3 , R^y and R^3 are all recursive substituents in certain claims. Typically, each of these may independently occur 20, 19, 18, 17, 16, 15, 14, 13, 12, 11, 10, 9, 8, 7, 6, 5, 4, 3, 2, 1, or 0, times in a given claim. More typically, each of these may independently occur 12 or fewer
5 times in a given claim. More typically yet, W^3 will occur 0 to 8 times, R^y will occur 0 to 6 times and R^3 will occur 0 to 10 times in a given claim. Even more typically, W^3 will occur 0 to 6 times, R^y will occur 0 to 4 times and R^3 will occur 0 to 8 times in a given claim.

Recursive substituents are an intended aspect of the invention. One of
10 ordinary skill in the art of medicinal chemistry understands the versatility of such substituents. To the degree that recursive substituents are present in an claim of the invention, the total number will be determined as set forth above.

Whenever a compound described herein is substituted with more than one of the same designated group, *e.g.*, " R^1 " or " R^{6a} ", then it will be understood
15 that the groups may be the same or different, *i.e.*, each group is independently selected. Wavy lines indicate the site of covalent bond attachments to the adjoining groups, moieties, or atoms.

The phosphonate group may be a phosphonate prodrug moiety. The prodrug moiety may be sensitive to hydrolysis, such as, but not limited to, a
20 pivaloyloxymethyl carbonate (POC) or POM group. Alternatively, the prodrug moiety may be sensitive to enzymatic potentiated cleavage, such as a lactate ester or a phosphonamidate-ester group.

In one embodiment of the invention the compound is not an anti-inflammatory compound; in another embodiment the compound is not an anti-
25 infective; in another embodiment the compound is not a compound that is active against immune-mediated conditions; in another embodiment the compound is not an anti-cancer compound; in another embodiment the compound is not a compound that is active against metabolic diseases; in another embodiment the compound is not a nucleoside; in another embodiment the compound is not a
30 IMPDH inhibitor; in another embodiment the compound is not an antimetabolite; in another embodiment the compound is not a PNP inhibitor; in another embodiment the compound is not a substituted compound of any one of

formulae 509-510, 556-557, and 559-562; and in another embodiment the compound is not a compound of any one of formulae 13-18, 72, 77-83, and 90-102.

5 In one embodiment of the invention, the compound is in an isolated and purified form. Generally, the term "isolated and purified" means that the compound is substantially free from biological materials (e.g. blood, tissue, cells, etc.). In one specific embodiment of the invention, the term means that the compound or conjugate of the invention is at least about 50 wt.% free from biological materials; in another specific embodiment, the term means that the
10 compound or conjugate of the invention is at least about 75 wt.% free from biological materials; in another specific embodiment, the term means that the compound or conjugate of the invention is at least about 90 wt.% free from biological materials; in another specific embodiment, the term means that the compound or conjugate of the invention is at least about 98 wt.% free from
15 biological materials; and in another embodiment, the term means that the compound or conjugate of the invention is at least about 99 wt.% free from biological materials. Cellular Accumulation

In one embodiment, the invention provides compounds capable of accumulating in human PBMC (peripheral blood mononuclear cells). PBMC refer to blood cells having round lymphocytes and monocytes. Physiologically,
25 PBMC are critical components of the mechanism against infection. PBMC may be isolated from heparinized whole blood of normal healthy donors or buffy coats, by standard density gradient centrifugation and harvested from the interface, washed (e.g. phosphate-buffered saline) and stored in freezing medium. PBMC may be cultured in multi-well plates. At various times of
30 culture, supernatant may be either removed for assessment, or cells may be harvested and analyzed (Smith R. et al (2003) *Blood* 102(7):2532-2540). The compounds of this claim may further comprise a phosphonate or phosphonate

prodrug. More typically, the phosphonate or phosphonate prodrug can have the structure A³ as described herein.

Typically, compounds of the invention demonstrate improved intracellular half-life of the compounds or intracellular metabolites of the compounds in human PBMC when compared to analogs of the compounds not having the phosphonate or phosphonate prodrug. Typically, the half-life is improved by at least about 50%, more typically at least in the range 50-100%, still more typically at least about 100%, more typically yet greater than about 100%.

In one embodiment of the invention the intracellular half-life of a metabolite of the compound in human PBMCs is improved when compared to an analog of the compound not having the phosphonate or phosphonate prodrug. In such claims, the metabolite may be generated intracellularly, *e.g.* generated within human PBMC. The metabolite may be a product of the cleavage of a phosphonate prodrug within human PBMCs. The phosphonate prodrug may be cleaved to form a metabolite having at least one negative charge at physiological pH. The phosphonate prodrug may be enzymatically cleaved within human PBMC to form a phosphonate having at least one active hydrogen atom of the form P-OH.

Stereoisomers

The compounds of the invention may have chiral centers, *e.g.*, chiral carbon or phosphorus atoms. The compounds of the invention thus include racemic mixtures of all stereoisomers, including enantiomers, diastereomers, and atropisomers. In addition, the compounds of the invention include enriched or resolved optical isomers at any or all asymmetric, chiral atoms. In other words, the chiral centers apparent from the depictions are provided as the chiral isomers or racemic mixtures. Both racemic and diastereomeric mixtures, as well as the individual optical isomers isolated or synthesized, substantially free of their enantiomeric or diastereomeric partners, are all within the scope of the invention. The racemic mixtures are separated into their individual, substantially optically pure isomers through well-known techniques such as, for example, the separation of diastereomeric salts formed with optically active adjuncts, *e.g.*,

acids or bases followed by conversion back to the optically active substances. In most instances, the desired optical isomer is synthesized by means of stereospecific reactions, beginning with the appropriate stereoisomer of the desired starting material.

5 The compounds of the invention can also exist as tautomeric isomers in certain cases. All though only one delocalized resonance structure may be depicted, all such forms are contemplated within the scope of the invention. For example, ene-amine tautomers can exist for purine, pyrimidine, imidazole, guanidine, amidine, and tetrazole systems and all their possible tautomeric forms
10 are within the scope of the invention.

Salts and Hydrates

 The compositions of this invention optionally comprise salts of the compounds herein, especially pharmaceutically acceptable non-toxic salts containing, for example, Na^+ , Li^+ , K^+ , Ca^{+2} and Mg^{+2} . Such salts may include
15 those derived by combination of appropriate cations such as alkali and alkaline earth metal ions or ammonium and quaternary amino ions with an acid anion moiety, typically a carboxylic acid. Monovalent salts are preferred if a water soluble salt is desired.

 Metal salts typically are prepared by reacting the metal hydroxide with a
20 compound of this invention. Examples of metal salts which are prepared in this way are salts containing Li^+ , Na^+ , and K^+ . A less soluble metal salt can be precipitated from the solution of a more soluble salt by addition of the suitable metal compound.

 In addition, salts may be formed from acid addition of certain organic
25 and inorganic acids, e.g., HCl , HBr , H_2SO_4 , H_3PO_4 or organic sulfonic acids, to basic centers, typically amines, or to acidic groups. Finally, it is to be understood that the compositions herein comprise compounds of the invention in their un-ionized, as well as zwitterionic form, and combinations with stoichiometric amounts of water as in hydrates.

30 Also included within the scope of this invention are the salts of the parental compounds with one or more amino acids. Any of the amino acids

described above are suitable, especially the naturally-occurring amino acids found as protein components, although the amino acid typically is one bearing a side chain with a basic or acidic group, *e.g.*, lysine, arginine or glutamic acid, or a neutral group such as glycine, serine, threonine, alanine, isoleucine, or leucine.

5 Methods of Inhibition of Viral Infections

Another aspect of the invention relates to methods of inhibiting viral infections, comprising the step of treating a sample or subject suspected of needing such inhibition with a composition of the invention.

10 Compositions of the invention may act as inhibitors of viral infections, or as intermediates for such inhibitors or have other utilities as described below. The inhibitors will bind to locations on the surface or in a cavity of a cell having a unique geometry. Compositions binding a cell may bind with varying degrees of reversibility. Those compounds binding substantially irreversibly are ideal candidates for use in this method of the invention. Once labeled, the

15 substantially irreversibly binding compositions are useful as probes for the detection of viruses. Accordingly, the invention relates to methods of detecting viruses in a sample or subject suspected of containing a virus, comprising the steps of: treating such a sample or subject with a composition comprising a compound of the invention bound to a label; and observing the effect of the

20 sample on the activity of the label. Suitable labels are well known in the diagnostics field and include stable free radicals, fluorophores, radioisotopes, enzymes, chemiluminescent groups and chromogens. The compounds herein are labeled in conventional fashion using functional groups such as hydroxyl or amino.

25 Within the context of the invention samples suspected of containing a virus include natural or man-made materials such as living organisms; tissue or cell cultures; biological samples such as biological material samples (blood, serum, urine, cerebrospinal fluid, tears, sputum, saliva, tissue samples, and the like); laboratory samples; food, water, or air samples; bioproduct samples such

30 as extracts of cells, particularly recombinant cells synthesizing a desired glycoprotein; and the like. Typically the sample will be suspected of containing

an organism which induces a viral infection, frequently a pathogenic organism such as an tumor virus. Samples can be contained in any medium including water and organic solvent\water mixtures. Samples include living organisms such as humans, and man made materials such as cell cultures.

5 The treating step of the invention comprises adding the composition of the invention to the sample or it comprises adding a precursor of the composition to the sample. The addition step comprises any method of administration as described above.

 If desired, the anti-virus activity of a compound of the invention after
10 application of the composition can be observed by any method including direct and indirect methods of detecting such activity. Quantitative, qualitative, and semiquantitative methods of determining such activity are all contemplated. Typically one of the screening methods described above are applied, however, any other method such as observation of the physiological properties of a living
15 organism are also applicable.

Screens for Antiviral Compounds

 Compositions of the invention are screened for antiviral activity by any of the conventional techniques for evaluating enzyme activity. Within the context of the invention, typically compositions are first screened for inhibitory
20 activity *in vitro* and compositions showing inhibitory activity are then screened for activity *in vivo*. Compositions having *in vitro* K_i (inhibitory constants) of less than about 5×10^{-6} M, typically less than about 1×10^{-7} M and preferably less than about 5×10^{-8} M are preferred for *in vivo* use.

 Useful *in vitro* screens have been described in detail and will not be
25 elaborated here.

Pharmaceutical Formulations

 The compounds of this invention are formulated with conventional carriers and excipients, which will be selected in accord with ordinary practice. Tablets will contain excipients, glidants, fillers, binders and the like. Aqueous
30 formulations are prepared in sterile form, and when intended for delivery by other than oral administration generally will be isotonic. All formulations will

optionally contain excipients such as those set forth in the Handbook of Pharmaceutical Excipients (1986). Excipients include ascorbic acid and other antioxidants, chelating agents such as EDTA, carbohydrates such as dextrin, hydroxyalkylcellulose, hydroxyalkylmethylcellulose, stearic acid and the like.

- 5 The pH of the formulations ranges from about 3 to about 11, but is ordinarily about 7 to 10.

While it is possible for the active ingredients to be administered alone it may be preferable to present them as pharmaceutical formulations. The formulations, both for veterinary and for human use, of the invention comprise at
10 least one active ingredient, as above defined, together with one or more acceptable carriers therefor and optionally other therapeutic ingredients. The carrier(s) must be "acceptable" in the sense of being compatible with the other ingredients of the formulation and physiologically innocuous to the recipient thereof.

- 15 The formulations include those suitable for the foregoing administration routes. The formulations may conveniently be presented in unit dosage form and may be prepared by any of the methods well known in the art of pharmacy. Techniques and formulations generally are found in Remington's Pharmaceutical Sciences (Mack Publishing Co., Easton, PA). Such methods include the step of
20 bringing into association the active ingredient with the carrier which constitutes one or more accessory ingredients. In general the formulations are prepared by uniformly and intimately bringing into association the active ingredient with liquid carriers or finely divided solid carriers or both, and then, if necessary, shaping the product.

- 25 Formulations of the present invention suitable for oral administration may be presented as discrete units such as capsules, cachets or tablets each containing a predetermined amount of the active ingredient; as a powder or granules; as a solution or a suspension in an aqueous or non-aqueous liquid; or as an oil-in-water liquid emulsion or a water-in-oil liquid emulsion. The active
30 ingredient may also be administered as a bolus, electuary or paste.

A tablet is made by compression or molding, optionally with one or more accessory ingredients. Compressed tablets may be prepared by compressing in a

suitable machine the active ingredient in a free-flowing form such as a powder or granules, optionally mixed with a binder, lubricant, inert diluent, preservative, surface active or dispersing agent. Molded tablets may be made by molding in a suitable machine a mixture of the powdered active ingredient moistened with an inert liquid diluent. The tablets may optionally be coated or scored and optionally are formulated so as to provide slow or controlled release of the active ingredient therefrom.

For administration to the eye or other external tissues *e.g.*, mouth and skin, the formulations are preferably applied as a topical ointment or cream containing the active ingredient(s) in an amount of, for example, 0.075 to 20% w/w (including active ingredient(s) in a range between 0.1% and 20% in increments of 0.1% w/w such as 0.6% w/w, 0.7% w/w, etc.), preferably 0.2 to 15% w/w and most preferably 0.5 to 10% w/w. When formulated in an ointment, the active ingredients may be employed with either a paraffinic or a water-miscible ointment base. Alternatively, the active ingredients may be formulated in a cream with an oil-in-water cream base.

If desired, the aqueous phase of the cream base may include, for example, at least 30% w/w of a polyhydric alcohol, *i.e.* an alcohol having two or more hydroxyl groups such as propylene glycol, butane 1,3-diol, mannitol, sorbitol, glycerol and polyethylene glycol (including PEG 400) and mixtures thereof. The topical formulations may desirably include a compound which enhances absorption or penetration of the active ingredient through the skin or other affected areas. Examples of such dermal penetration enhancers include dimethyl sulphoxide and related analogs.

The oily phase of the emulsions of this invention may be constituted from known ingredients in a known manner. While the phase may comprise merely an emulsifier (otherwise known as an emulgent), it desirably comprises a mixture of at least one emulsifier with a fat or an oil or with both a fat and an oil. Preferably, a hydrophilic emulsifier is included together with a lipophilic emulsifier which acts as a stabilizer. It is also preferred to include both an oil and a fat. Together, the emulsifier(s) with or without stabilizer(s) make up the so-called emulsifying wax, and the wax together with the oil and fat make up the

so-called emulsifying ointment base which forms the oily dispersed phase of the cream formulations.

Emulgents and emulsion stabilizers suitable for use in the formulation of the invention include Tween[®] 60, Span[®] 80, cetostearyl alcohol, benzyl
5 alcohol, myristyl alcohol, glyceryl mono-stearate and sodium lauryl sulfate.

The choice of suitable oils or fats for the formulation is based on achieving the desired cosmetic properties. The cream should preferably be a non-greasy, non-staining and washable product with suitable consistency to avoid leakage from tubes or other containers. Straight or branched chain, mono-
10 or dibasic alkyl esters such as di-isoadipate, isocetyl stearate, propylene glycol diester of coconut fatty acids, isopropyl myristate, decyl oleate, isopropyl palmitate, butyl stearate, 2-ethylhexyl palmitate or a blend of branched chain esters known as Crodamol CAP may be used, the last three being preferred
15 esters. These may be used alone or in combination depending on the properties required. Alternatively, high melting point lipids such as white soft paraffin and/or liquid paraffin or other mineral oils are used.

Pharmaceutical formulations according to the present invention comprise one or more compounds of the invention together with one or more pharmaceutically acceptable carriers or excipients and optionally other
20 therapeutic agents. Pharmaceutical formulations containing the active ingredient may be in any form suitable for the intended method of administration. When used for oral use for example, tablets, troches, lozenges, aqueous or oil suspensions, dispersible powders or granules, emulsions, hard or soft capsules, syrups or elixirs may be prepared. Compositions intended for oral use may be
25 prepared according to any method known to the art for the manufacture of pharmaceutical compositions and such compositions may contain one or more agents including sweetening agents, flavoring agents, coloring agents and preserving agents, in order to provide a palatable preparation. Tablets containing the active ingredient in admixture with non-toxic pharmaceutically acceptable
30 excipient which are suitable for manufacture of tablets are acceptable. These excipients may be, for example, inert diluents, such as calcium or sodium carbonate, lactose, lactose monohydrate, croscarmellose sodium, povidone,

calcium or sodium phosphate; granulating and disintegrating agents, such as maize starch, or alginic acid; binding agents, such as cellulose, microcrystalline cellulose, starch, gelatin or acacia; and lubricating agents, such as magnesium stearate, stearic acid or talc. Tablets may be uncoated or may be coated by
5 known techniques including microencapsulation to delay disintegration and adsorption in the gastrointestinal tract and thereby provide a sustained action over a longer period. For example, a time delay material such as glyceryl monostearate or glyceryl distearate alone or with a wax may be employed.

Formulations for oral use may be also presented as hard gelatin capsules
10 where the active ingredient is mixed with an inert solid diluent, for example calcium phosphate or kaolin, or as soft gelatin capsules wherein the active ingredient is mixed with water or an oil medium, such as peanut oil, liquid paraffin or olive oil.

Aqueous suspensions of the invention contain the active materials in
15 admixture with excipients suitable for the manufacture of aqueous suspensions. Such excipients include a suspending agent, such as sodium carboxymethylcellulose, methylcellulose, hydroxypropyl methylcellulose, sodium alginate, polyvinylpyrrolidone, gum tragacanth and gum acacia, and dispersing or wetting agents such as a naturally occurring phosphatide (*e.g.*,
20 lecithin), a condensation product of an alkylene oxide with a fatty acid (*e.g.*, polyoxyethylene stearate), a condensation product of ethylene oxide with a long chain aliphatic alcohol (*e.g.*, heptadecaethyleneoxycetanol), a condensation product of ethylene oxide with a partial ester derived from a fatty acid and a hexitol anhydride (*e.g.*, polyoxyethylene sorbitan monooleate). The aqueous
25 suspension may also contain one or more preservatives such as ethyl or n-propyl p-hydroxy-benzoate, one or more coloring agents, one or more flavoring agents and one or more sweetening agents, such as sucrose or saccharin.

Oil suspensions may be formulated by suspending the active ingredient in a vegetable oil, such as arachis oil, olive oil, sesame oil or coconut oil, or in a
30 mineral oil such as liquid paraffin. The oral suspensions may contain a thickening agent, such as beeswax, hard paraffin or cetyl alcohol. Sweetening agents, such as those set forth above, and flavoring agents may be added to

provide a palatable oral preparation. These compositions may be preserved by the addition of an antioxidant such as ascorbic acid.

Dispersible powders and granules of the invention suitable for preparation of an aqueous suspension by the addition of water provide the active
5 ingredient in admixture with a dispersing or wetting agent, a suspending agent, and one or more preservatives. Suitable dispersing or wetting agents and suspending agents are exemplified by those disclosed above. Additional excipients, for example sweetening, flavoring and coloring agents, may also be present.

10 The pharmaceutical compositions of the invention may also be in the form of oil-in-water emulsions. The oily phase may be a vegetable oil, such as olive oil or arachis oil, a mineral oil, such as liquid paraffin, or a mixture of these. Suitable emulsifying agents include naturally-occurring gums, such as gum acacia and gum tragacanth, naturally occurring phosphatides, such as
15 soybean lecithin, esters or partial esters derived from fatty acids and hexitol anhydrides, such as sorbitan monooleate, and condensation products of these partial esters with ethylene oxide, such as polyoxyethylene sorbitan monooleate. The emulsion may also contain sweetening and flavoring agents. Syrups and elixirs may be formulated with sweetening agents, such as glycerol, sorbitol or
20 sucrose. Such formulations may also contain a demulcent, a preservative, a flavoring or a coloring agent.

The pharmaceutical compositions of the invention may be in the form of a sterile injectable preparation, such as a sterile injectable aqueous or oleaginous suspension. This suspension may be formulated according to the known art using
25 those suitable dispersing or wetting agents and suspending agents which have been mentioned above. The sterile injectable preparation may also be a sterile injectable solution or suspension in a non-toxic parenterally acceptable diluent or solvent, such as a solution in 1,3-butane-diol or prepared as a lyophilized powder. Among the acceptable vehicles and solvents that may be employed are
30 water, Ringer's solution and isotonic sodium chloride solution. In addition, sterile fixed oils may conventionally be employed as a solvent or suspending medium. For this purpose any bland fixed oil may be employed including

synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid may likewise be used in the preparation of injectables.

The amount of active ingredient that may be combined with the carrier material to produce a single dosage form will vary depending upon the host
5 treated and the particular mode of administration. For example, a time-release formulation intended for oral administration to humans may contain approximately 1 to 1000 mg of active material compounded with an appropriate and convenient amount of carrier material which may vary from about 5 to about 95% of the total compositions (weight:weight). The pharmaceutical composition
10 can be prepared to provide easily measurable amounts for administration. For example, an aqueous solution intended for intravenous infusion may contain from about 3 to 500 µg of the active ingredient per milliliter of solution in order that infusion of a suitable volume at a rate of about 30 mL/hr can occur.

Formulations suitable for administration to the eye include eye drops
15 wherein the active ingredient is dissolved or suspended in a suitable carrier, especially an aqueous solvent for the active ingredient. The active ingredient is preferably present in such formulations in a concentration of 0.5 to 20%, advantageously 0.5 to 10% particularly about 1.5% w/w.

Formulations suitable for topical administration in the mouth include
20 lozenges comprising the active ingredient in a flavored basis, usually sucrose and acacia or tragacanth; pastilles comprising the active ingredient in an inert basis such as gelatin and glycerin, or sucrose and acacia; and mouthwashes comprising the active ingredient in a suitable liquid carrier.

Formulations for rectal administration may be presented as a suppository
25 with a suitable base comprising for example cocoa butter or a salicylate.

Formulations suitable for intrapulmonary or nasal administration have a particle size for example in the range of 0.1 to 500 microns (including particle sizes in a range between 0.1 and 500 microns in increments microns such as 0.5, 1, 30 microns, 35 microns, etc.), which is administered by rapid inhalation
30 through the nasal passage or by inhalation through the mouth so as to reach the alveolar sacs. Suitable formulations include aqueous or oily solutions of the active ingredient. Formulations suitable for aerosol or dry powder

administration may be prepared according to conventional methods and may be delivered with other therapeutic agents such as compounds heretofore used in the treatment or prophylaxis of viral infections as described below.

Formulations suitable for vaginal administration may be presented as pessaries, tampons, creams, gels, pastes, foams or spray formulations containing in addition to the active ingredient such carriers as are known in the art to be appropriate.

Formulations suitable for parenteral administration include aqueous and non-aqueous sterile injection solutions which may contain anti-oxidants, buffers, bacteriostats and solutes which render the formulation isotonic with the blood of the intended recipient; and aqueous and non-aqueous sterile suspensions which may include suspending agents and thickening agents.

The formulations are presented in unit-dose or multi-dose containers, for example sealed ampoules and vials, and may be stored in a freeze-dried (lyophilized) condition requiring only the addition of the sterile liquid carrier, for example water for injection, immediately prior to use. Extemporaneous injection solutions and suspensions are prepared from sterile powders, granules and tablets of the kind previously described. Preferred unit dosage formulations are those containing a daily dose or unit daily sub-dose, as herein above recited, or an appropriate fraction thereof, of the active ingredient.

It should be understood that in addition to the ingredients particularly mentioned above the formulations of this invention may include other agents conventional in the art having regard to the type of formulation in question, for example those suitable for oral administration may include flavoring agents.

The invention further provides veterinary compositions comprising at least one active ingredient as above defined together with a veterinary carrier therefor.

Veterinary carriers are materials useful for the purpose of administering the composition and may be solid, liquid or gaseous materials which are otherwise inert or acceptable in the veterinary art and are compatible with the active ingredient. These veterinary compositions may be administered orally, parenterally or by any other desired route.

Compounds of the invention can also be formulated to provide controlled release of the active ingredient to allow less frequent dosing or to improve the pharmacokinetic or toxicity profile of the active ingredient. Accordingly, the invention also provided compositions comprising one or more compounds of the invention formulated for sustained or controlled release.

Effective dose of active ingredient depends at least on the nature of the condition being treated, toxicity, whether the compound is being used prophylactically (lower doses) or against an active viral infection, the method of delivery, and the pharmaceutical formulation, and will be determined by the clinician using conventional dose escalation studies. It can be expected to be from about 0.0001 to about 100 mg/kg body weight per day. Typically, from about 0.01 to about 10 mg/kg body weight per day. More typically, from about .01 to about 5 mg/kg body weight per day. More typically, from about .05 to about 0.5 mg/kg body weight per day. For example, the daily candidate dose for an adult human of approximately 70 kg body weight will range from 1 mg to 1000 mg, preferably between 5 mg and 500 mg, and may take the form of single or multiple doses.

Routes of Administration

One or more compounds of the invention (herein referred to as the active ingredients) are administered by any route appropriate to the condition to be treated. Suitable routes include oral, rectal, nasal, topical (including buccal and sublingual), vaginal and parenteral (including subcutaneous, intramuscular, intravenous, intradermal, intrathecal and epidural), and the like. It will be appreciated that the preferred route may vary with for example the condition of the recipient. An advantage of the compounds of this invention is that they are orally bioavailable and can be dosed orally.

Combination Therapy

Active ingredients of the invention are also used in combination with other active ingredients. Such combinations are selected based on the condition to be treated, cross-reactivities of ingredients and pharmaco-properties of the combination. For example, when treating a viral infection the compositions of

the invention can be combined with other agents that are effective to treat a viral infection (such as other antiviral agents).

It is also possible to combine any compound of the invention with one or more other active ingredients in a unitary dosage form for simultaneous or sequential administration to a patient. The combination therapy may be administered as a simultaneous or sequential regimen. When administered sequentially, the combination may be administered in two or more administrations.

The combination therapy may provide "synergy" and "synergistic effect", *i.e.* the effect achieved when the active ingredients used together is greater than the sum of the effects that results from using the compounds separately. A synergistic effect may be attained when the active ingredients are: (1) co-formulated and administered or delivered simultaneously in a combined formulation; (2) delivered by alternation or in parallel as separate formulations; or (3) by some other regimen. When delivered in alternation therapy, a synergistic effect may be attained when the compounds are administered or delivered sequentially, *e.g.*, in separate tablets, pills or capsules, or by different injections in separate syringes. In general, during alternation therapy, an effective dosage of each active ingredient is administered sequentially, *i.e.* serially, whereas in combination therapy, effective dosages of two or more active ingredients are administered together.

Metabolites of the Compounds of the Invention

Also falling within the scope of this invention are the *in vivo* metabolic products of the compounds described herein. Such products may result for example from the oxidation, reduction, hydrolysis, amidation, esterification and the like of the administered compound, primarily due to enzymatic processes. Accordingly, the invention includes compounds produced by a process comprising contacting a compound of this invention with a mammal for a period of time sufficient to yield a metabolic product thereof. Such products typically are identified by preparing a radiolabelled (*e.g.*, C¹⁴ or H³) compound of the invention, administering it parenterally in a detectable dose (*e.g.*, greater than

about 0.5 mg/kg) to an animal such as rat, mouse, guinea pig, monkey, or to man, allowing sufficient time for metabolism to occur (typically about 30 seconds to 30 hours) and isolating its conversion products from the urine, blood or other biological samples. These products are easily isolated since they are labeled (others are isolated by the use of antibodies capable of binding epitopes surviving in the metabolite). The metabolite structures are determined in conventional fashion, *e.g.*, by MS or NMR analysis. In general, analysis of metabolites is done in the same way as conventional drug metabolism studies well-known to those skilled in the art. The conversion products, so long as they are not otherwise found *in vivo*, are useful in diagnostic assays for therapeutic dosing of the compounds of the invention even if they possess no antiviral activity of their own.

Recipes and methods for determining stability of compounds in surrogate gastrointestinal secretions are known. Compounds are defined herein as stable in the gastrointestinal tract where less than about 50 mole percent of the protected groups are deprotected in surrogate intestinal or gastric juice upon incubation for 1 hour at 37 °C. Simply because the compounds are stable to the gastrointestinal tract does not mean that they cannot be hydrolyzed *in vivo*. The phosphonate prodrugs of the invention typically will be stable in the digestive system but are substantially hydrolyzed to the parental drug in the digestive lumen, liver or other metabolic organ, or within cells in general.

Antiviral Activity

The antiviral activity of a compound of the invention can be measured using standard screening protocols that are known. For example, the antiviral activity of a compound can be measured in a cell culture assay using the following general protocol.

Antiviral Cell Culture Assay

The assay is based on quantification of the antiviral effect by a colorimetric detection of the viability of virus-infected cells in the presence or absence of tested inhibitors. The compound-induced cell death is determined using a metabolic

substrate 2,3-bis(2-methoxy-4-nitro-5-sulphophenyl)-2H-tetrazolium-5-carboxanilide (XTT) which is converted only by intact cells into a product with specific absorption characteristics as described by Weislow OS, Kiser R, Fine DL, Bader J, Shoemaker RH and Boyd MR (1989) *J Natl Cancer Inst* 81, 577.

5 Assay protocol for determination of EC50:

1. Maintain MT2 cells in RPMI-1640 medium supplemented with 5% fetal bovine serum and antibiotics.
2. Infect the cells with the viral agent for 3 hours at 37 °C using the virus inoculum corresponding to a multiplicity of infection equal to 0.01.
- 10 3. Distribute the infected cells into a 96-well plate (20,000 cells in 100 µl/well) and add various concentrations of the tested inhibitor in triplicate (100 µl/well in culture media). Include untreated infected and untreated mock-infected control cells.
4. Incubate the cells for 5 days at 37 °C.
- 15 5. Prepare a compound solution (6 ml per assay plate) at a concentration of 2mg/ml in a phosphate-buffered saline pH 7.4. Heat the solution in water-bath for 5 min at 55 °C. Add 50 µl of N-methylphenazonium methasulfate (5 µg/ml) per 6 ml of XTT solution.
6. Remove 100 µl media from each well on the assay plate.
- 20 7. Add 100 µl of the XTT substrate solution per well and incubate at 37 °C for 45 to 60 min in a CO₂ incubator.
8. Add 20 µl of 2% Triton X-100 per well to inactivate the virus.
9. Read the absorbance at 450 nm with subtracting off the background absorbance at 650 nm.
- 25 10. Plot the percentage absorbance relative to untreated control and estimate the EC50 value as drug concentration resulting in a 50% protection of the infected cells.

30 The cytotoxicity of a compound of the invention can be determined using the following general protocol.

Cytotoxicity Cell Culture Assay (Determination of CC50):

The assay is based on the evaluation of cytotoxic effect of tested compounds using a metabolic substrate.

Assay protocol for determination of CC50:

- 5 1. Maintain MT-2 cells in RPMI-1640 medium supplemented with 5% fetal bovine serum and antibiotics.
2. Distribute the cells into a 96-well plate (20,000 cell in 100 µl media per well) and add various concentrations of the tested compound in triplicate (100 µl/well). Include untreated control.
- 10 3. Incubate the cells for 5 days at 37 °C.
4. Prepare XTT solution (6 ml per assay plate) in dark at a concentration of 2mg/ml in a phosphate-buffered saline pH 7.4. Heat the solution in a water-bath at 55°C for 5 min. Add 50 µl of N-methylphenazonium methasulfate (5 µg/ml) per 6 ml of XTT solution.
- 15 5. Remove 100 µl media from each well on the assay plate and add 100 µl of the XTT substrate solution per well. Incubate at 37 °C for 45 to 60 min in a CO₂ incubator.
6. Add 20 µl of 2% Triton X-100 per well to stop the metabolic conversion of XTT.
- 20 7. Read the absorbance at 450 nm with subtracting off the background at 650 nm.

Exemplary Methods of Making the Compounds of the Invention.

The invention also relates to methods of making the compositions of the invention. The compositions are prepared by any of the applicable techniques of
30 organic synthesis. Many such techniques are well known in the art. However,

many of the known techniques are elaborated in Compendium of Organic Synthetic Methods (John Wiley & Sons, New York), Vol. 1, Ian T. Harrison and Shuyen Harrison, 1971; Vol. 2, Ian T. Harrison and Shuyen Harrison, 1974; Vol. 3, Louis S. Hegedus and Leroy Wade, 1977; Vol. 4, Leroy G. Wade, jr., 1980; 5 Vol. 5, Leroy G. Wade, Jr., 1984; and Vol. 6, Michael B. Smith; as well as March, J., Advanced Organic Chemistry, Third Edition, (John Wiley & Sons, New York, 1985), Comprehensive Organic Synthesis. Selectivity, Strategy & Efficiency in Modern Organic Chemistry. In 9 Volumes, Barry M. Trost, Editor-in-Chief (Pergamon Press, New York, 1993 printing).

10 A number of exemplary methods for the preparation of the compositions of the invention are provided below. These methods are intended to illustrate the nature of such preparations are not intended to limit the scope of applicable methods.

Generally, the reaction conditions such as temperature, reaction time, 15 solvents, work-up procedures, and the like, will be those common in the art for the particular reaction to be performed. The cited reference material, together with material cited therein, contains detailed descriptions of such conditions. Typically the temperatures will be -100°C to 200°C, solvents will be aprotic or protic, and reaction times will be 10 seconds to 10 days. Work-up typically 20 consists of quenching any unreacted reagents followed by partition between a water/organic layer system (extraction) and separating the layer containing the product.

Oxidation and reduction reactions are typically carried out at temperatures near room temperature (about 20 °C), although for metal hydride 25 reductions frequently the temperature is reduced to 0 °C to -100 °C, solvents are typically aprotic for reductions and may be either protic or aprotic for oxidations. Reaction times are adjusted to achieve desired conversions.

Condensation reactions are typically carried out at temperatures near room temperature, although for non-equilibrating, kinetically controlled 30 condensations reduced temperatures (0 °C to -100 °C) are also common. Solvents can be either protic (common in equilibrating reactions) or aprotic (common in kinetically controlled reactions).

Standard synthetic techniques such as azeotropic removal of reaction by-products and use of anhydrous reaction conditions (*e.g.*, inert gas environments) are common in the art and will be applied when applicable.

Schemes and Examples

5 General aspects of these exemplary methods are described below and in the Examples. Each of the products of the following processes is optionally separated, isolated, and/or purified prior to its use in subsequent processes.

30 The terms "treated", "treating", "treatment", and the like, when used in connection with a chemical synthetic operation, mean contacting, mixing, reacting, allowing to react, bringing into contact, and other terms common in the

art for indicating that one or more chemical entities is treated in such a manner as to convert it to one or more other chemical entities. This means that "treating compound one with compound two" is synonymous with "allowing compound one to react with compound two", "contacting compound one with compound two", "reacting compound one with compound two", and other expressions common in the art of organic synthesis for reasonably indicating that compound one was "treated", "reacted", "allowed to react", etc., with compound two. For example, treating indicates the reasonable and usual manner in which organic chemicals are allowed to react. Normal concentrations (0.01M to 10M, typically 0.1M to 1M), temperatures (-100 °C to 250 °C, typically -78 °C to 150 °C, more typically -78 °C to 100 °C, still more typically 0 °C to 100 °C), reaction vessels (typically glass, plastic, metal), solvents, pressures, atmospheres (typically air for oxygen and water insensitive reactions or nitrogen or argon for oxygen or water sensitive), etc., are intended unless otherwise indicated. The knowledge of similar reactions known in the art of organic synthesis are used in selecting the conditions and apparatus for "treating" in a given process. In particular, one of ordinary skill in the art of organic synthesis selects conditions and apparatus reasonably expected to successfully carry out the chemical reactions of the described processes based on the knowledge in the art.

Modifications of each of the exemplary schemes and in the examples (hereafter "exemplary schemes") leads to various analogs of the specific exemplary materials produce. The above-cited citations describing suitable methods of organic synthesis are applicable to such modifications.

In each of the exemplary schemes it may be advantageous to separate reaction products from one another and/or from starting materials. The desired products of each step or series of steps is separated and/or purified (hereinafter separated) to the desired degree of homogeneity by the techniques common in the art. Typically such separations involve multiphase extraction, crystallization from a solvent or solvent mixture, distillation, sublimation, or chromatography. Chromatography can involve any number of methods including, for example: reverse-phase and normal phase; size exclusion; ion exchange; high, medium, and low pressure liquid chromatography methods and apparatus; small scale

analytical; simulated moving bed (SMB) and preparative thin or thick layer chromatography, as well as techniques of small scale thin layer and flash chromatography.

Another class of separation methods involves treatment of a mixture with a reagent selected to bind to or render otherwise separable a desired product, unreacted starting material, reaction by product, or the like. Such reagents include adsorbents or absorbents such as activated carbon, molecular sieves, ion exchange media, or the like. Alternatively, the reagents can be acids in the case of a basic material, bases in the case of an acidic material, binding reagents such as antibodies, binding proteins, selective chelators such as crown ethers, liquid/liquid ion extraction reagents (LIX), or the like.

Selection of appropriate methods of separation depends on the nature of the materials involved. For example, boiling point, and molecular weight in distillation and sublimation, presence or absence of polar functional groups in chromatography, stability of materials in acidic and basic media in multiphase extraction, and the like. One skilled in the art will apply techniques most likely to achieve the desired separation.

A single stereoisomer, *e.g.*, an enantiomer, substantially free of its stereoisomer may be obtained by resolution of the racemic mixture using a method such as formation of diastereomers using optically active resolving agents (Stereochemistry of Carbon Compounds, (1962) by E. L. Eliel, McGraw Hill; Lochmuller, C. H., (1975) *J. Chromatogr.*, 113:(3) 283-302). Racemic mixtures of chiral compounds of the invention can be separated and isolated by any suitable method, including: (1) formation of ionic, diastereomeric salts with chiral compounds and separation by fractional crystallization or other methods, (2) formation of diastereomeric compounds with chiral derivatizing reagents, separation of the diastereomers, and conversion to the pure stereoisomers, and (3) separation of the substantially pure or enriched stereoisomers directly under chiral conditions.

Under method (1), diastereomeric salts can be formed by reaction of enantiomerically pure chiral bases such as brucine, quinine, ephedrine, strychnine, α -methyl- β -phenylethylamine (amphetamine), and the like with

asymmetric compounds bearing acidic functionality, such as carboxylic acid and sulfonic acid. The diastereomeric salts may be induced to separate by fractional crystallization or ionic chromatography. For separation of the optical isomers of amino compounds, addition of chiral carboxylic or sulfonic acids, such as
5 camphorsulfonic acid, tartaric acid, mandelic acid, or lactic acid can result in formation of the diastereomeric salts.

Alternatively, by method (2), the substrate to be resolved is reacted with one enantiomer of a chiral compound to form a diastereomeric pair (Eliel, E. and Wilen, S. (1994) Stereochemistry of Organic Compounds, John Wiley & Sons,
10 Inc., p. 322). Diastereomeric compounds can be formed by reacting asymmetric compounds with enantiomerically pure chiral derivatizing reagents, such as menthyl derivatives, followed by separation of the diastereomers and hydrolysis to yield the free, enantiomerically enriched xanthene. A method of determining optical purity involves making chiral esters, such as a menthyl ester, *e.g.*, (-)
15 menthyl chloroformate in the presence of base, or Mosher ester, α -methoxy- α -(trifluoromethyl)phenyl acetate (Jacob III. (1982) *J. Org. Chem.* 47:4165), of the racemic mixture, and analyzing the NMR spectrum for the presence of the two atropisomeric diastereomers. Stable diastereomers of atropisomeric compounds can be separated and isolated by normal- and reverse-phase chromatography
20 following methods for separation of atropisomeric naphthyl-isoquinolines (Hoye, T., WO 96/15111). By method (3), a racemic mixture of two enantiomers can be separated by chromatography using a chiral stationary phase (Chiral Liquid Chromatography (1989) W. J. Lough, Ed. Chapman and Hall, New York; Okamoto, (1990) *J. of Chromatogr.* 513:375-378). Enriched or
25 purified enantiomers can be distinguished by methods used to distinguish other chiral molecules with asymmetric carbon atoms, such as optical rotation and circular dichroism.

Examples General Section

A number of exemplary methods for the preparation of
30 compounds of the invention are provided herein, for example, in the Examples hereinbelow.. These methods are intended to illustrate the nature of such preparations are not intended to limit the scope of applicable methods. Certain

compounds of the invention can be used as intermediates for the preparation of other compounds of the invention. For example, the interconversion of various phosphonate compounds of the invention is illustrated below.

5 Interconversions of the Phosphonates R-LINK-P(O)(OR¹)₂, R-LINK-P(O)(OR¹)(OH) AND R-LINK-P(O)(OH)₂.

The following schemes 32-38 described the preparation of phosphonate esters of the general structure R-link-P(O)(OR¹)₂, in which the groups R¹ may be the same or different. The R¹ groups attached to a phosphonate ester, or to
10 precursors thereto, may be changed using established chemical transformations. The interconversion reactions of phosphonates are illustrated in Scheme S32. The group R in Scheme 32 represents the substructure, *i.e.* the drug "scaffold, to which the substituent link-P(O)(OR¹)₂ is attached, either in the compounds of the invention, or in precursors thereto. At the point in the synthetic route of
15 conducting a phosphonate interconversion, certain functional groups in R may be protected. The methods employed for a given phosphonate transformation depend on the nature of the substituent R¹, and of the substrate to which the phosphonate group is attached. The preparation and hydrolysis of phosphonate esters is described in Organic Phosphorus Compounds, G. M. Kosolapoff, L.
20 Macir, eds, Wiley, 1976, p. 9ff.

In general, synthesis of phosphonate esters is achieved by coupling a nucleophile amine or alcohol with the corresponding activated phosphonate electrophilic precursor. For example, chlorophosphonate addition on to 5'-hydroxy of nucleoside is a well known method for preparation of nucleoside
25 phosphate monoesters. The activated precursor can be prepared by several well known methods. Chlorophosphonates useful for synthesis of the prodrugs are prepared from the substituted-1,3-propanediol (Wissner, et al, (1992) *J. Med Chem.* 35:1650). Chlorophosphonates are made by oxidation of the corresponding chlorophospholanes (Anderson, et al, (1984) *J. Org. Chem.*
30 49:1304) which are obtained by reaction of the substituted diol with phosphorus trichloride. Alternatively, the chlorophosphonate agent is made by treating substituted-1,3-diols with phosphorus oxychloride (Patois, et al, (1990) *J. Chem.*

Soc. Perkin Trans. I, 1577). Chlorophosphonate species may also be generated in situ from corresponding cyclic phosphites (Silverburg, et al., (1996) *Tetrahedron lett.*, 37:771-774), which in turn can be either made from chlorophospholane or phosphoramidate intermediate. Phosphoroflouridate intermediate prepared either
5 from pyrophosphate or phosphoric acid may also act as precursor in preparation of cyclic prodrugs (Watanabe et al., (1988) *Tetrahedron lett.*, 29:5763-66).

Phosphonate prodrugs of the present invention may also be prepared from the free acid by Mitsunobu reactions (Mitsunobu, (1981) *Synthesis*, 1; Campbell, (1992) *J. Org. Chem.* 57:6331), and other acid coupling reagents
10 including, but not limited to, carbodiimides (Alexander, et al, (1994) *Collect. Czech. Chem. Commun.* 59:1853; Casara et al, (1992) *Bioorg. Med. Chem. Lett.* 2:145; Ohashi et al, (1988) *Tetrahedron Lett.*, 29:1189), and benzotriazolyloxytris-(dimethylamino)phosphonium salts (Campagne et al (1993) *Tetrahedron Lett.* 34:6743).

15 Aryl halides undergo Ni^{+2} catalyzed reaction with phosphite derivatives to give aryl phosphonate containing compounds (Balthazar, et al (1980) *J. Org. Chem.* 45:5425). Phosphonates may also be prepared from the chlorophosphonate in the presence of a palladium catalyst using aromatic triflates (Petrakis et al (1987) *J. Am. Chem. Soc.* 109:2831; Lu et al (1987)
20 *Synthesis* 726). In another method, aryl phosphonate esters are prepared from aryl phosphates under anionic rearrangement conditions (Melvin (1981) *Tetrahedron Lett.* 22:3375; Casteel et al (1991) *Synthesis*, 691). N-Alkoxy aryl salts with alkali metal derivatives of cyclic alkyl phosphonate provide general synthesis for heteroaryl-2-phosphonate linkers (Redmore (1970) *J. Org. Chem.*
25 35:4114). These above mentioned methods can also be extended to compounds where the W^5 group is a heterocycle. Cyclic-1,3-propanyl prodrugs of phosphonates are also synthesized from phosphonic diacids and substituted propane-1,3-diols using a coupling reagent such as 1,3-dicyclohexylcarbodiimide (DCC) in presence of a base (e.g., pyridine). Other
30 carbodiimide based coupling agents like 1,3-disopropylcarbodiimide or water soluble reagent, 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide hydrochloride (EDCI) can also be utilized for the synthesis of cyclic phosphonate prodrugs.

The conversion of a phosphonate diester S32.1 into the corresponding phosphonate monoester S32.2 (Scheme 32, Reaction 1) is accomplished by a number of methods. For example, the ester S32.1 in which R¹ is an aralkyl group such as benzyl, is converted into the monoester compound S32.2 by reaction with a tertiary organic base such as diazabicyclooctane (DABCO) or quinuclidine, as described in *J. Org. Chem.* (1995) 60:2946. The reaction is performed in an inert hydrocarbon solvent such as toluene or xylene, at about 110 °C. The conversion of the diester S32.1 in which R¹ is an aryl group such as phenyl, or an alkenyl group such as allyl, into the monoester S32.2 is effected by treatment of the ester S32.1 with a base such as aqueous sodium hydroxide in acetonitrile or lithium hydroxide in aqueous tetrahydrofuran. Phosphonate diesters S32.1 in which one of the groups R¹ is aralkyl, such as benzyl, and the other is alkyl, is converted into the monoesters S32.2 in which R¹ is alkyl by hydrogenation, for example using a palladium on carbon catalyst. Phosphonate diesters in which both of the groups R¹ are alkenyl, such as allyl, is converted into the monoester S32.2 in which R¹ is alkenyl, by treatment with chlorotris(triphenylphosphine)rhodium (Wilkinson's catalyst) in aqueous ethanol at reflux, optionally in the presence of diazabicyclooctane, for example by using the procedure described in *J. Org. Chem.* (1973) 38:3224, for the cleavage of allyl carboxylates.

The conversion of a phosphonate diester S32.1 or a phosphonate monoester S32.2 into the corresponding phosphonic acid S32.3 (Scheme 32, Reactions 2 and 3) can be effected by reaction of the diester or the monoester with trimethylsilyl bromide, as described in *J. Chem. Soc., Chem. Comm.*, (1979) 739. The reaction is conducted in an inert solvent such as, for example, dichloromethane, optionally in the presence of a silylating agent such as bis(trimethylsilyl)trifluoroacetamide, at ambient temperature. A phosphonate monoester S32.2 in which R¹ is aralkyl such as benzyl, is converted into the corresponding phosphonic acid S32.3 by hydrogenation over a palladium catalyst, or by treatment with hydrogen chloride in an ethereal solvent such as dioxane. A phosphonate monoester S32.2 in which R¹ is alkenyl such as, for example, allyl, is converted into the phosphonic acid S32.3 by reaction with

Wilkinson's catalyst in an aqueous organic solvent, for example in 15% aqueous acetonitrile, or in aqueous ethanol, for example using the procedure described in *Helv. Chim. Acta.* (1985) 68:618. Palladium catalyzed hydrogenolysis of phosphonate esters S32.1 in which R¹ is benzyl is described in *J. Org. Chem.*

- 5 (1959) 24:434. Platinum-catalyzed hydrogenolysis of phosphonate esters S32.1 in which R¹ is phenyl is described in *J. Am. Chem. Soc.* (1956) 78:2336.

The conversion of a phosphonate monoester S32.2 into a phosphonate diester S32.1 (Scheme 32, Reaction 4) in which the newly introduced R¹ group is alkyl, aralkyl, haloalkyl such as chloroethyl, or aralkyl is effected by a number
10 of reactions in which the substrate S32.2 is reacted with a hydroxy compound R¹OH, in the presence of a coupling agent. Typically, the second phosphonate ester group is different than the first introduced phosphonate ester group, *i.e.* R¹ is followed by the introduction of R² where each of R¹ and R² is alkyl, aralkyl, haloalkyl such as chloroethyl, or aralkyl (Scheme 32, Reaction 4a) whereby
15 S32.2 is converted to S32.1 a. Suitable coupling agents are those employed for the preparation of carboxylate esters, and include a carbodiimide such as dicyclohexylcarbodiimide, in which case the reaction is preferably conducted in a basic organic solvent such as pyridine, or (benzotriazol-1-
20 yloxy)tripyrrolidinophosphonium hexafluorophosphate (PYBOP, Sigma), in which case the reaction is performed in a polar solvent such as dimethylformamide, in the presence of a tertiary organic base such as diisopropylethylamine, or Aldrithiol-2 (Aldrich) in which case the reaction is conducted in a basic solvent such as pyridine, in the presence of a triaryl phosphine such as triphenylphosphine. Alternatively, the conversion of the
25 phosphonate monoester S32.2 to the diester S32.1 is effected by the use of the Mitsunobu reaction, as described above (Scheme 7). The substrate is reacted with the hydroxy compound R¹OH, in the presence of diethyl azodicarboxylate and a triarylphosphine such as triphenyl phosphine. Alternatively, the phosphonate monoester S32.2 is transformed into the phosphonate diester S32.1,
30 in which the introduced R¹ group is alkenyl or aralkyl, by reaction of the monoester with the halide R¹Br, in which R¹ is as alkenyl or aralkyl. The alkylation reaction is conducted in a polar organic solvent such as

dimethylformamide or acetonitrile, in the presence of a base such as cesium carbonate. Alternatively, the phosphonate monoester is transformed into the phosphonate diester in a two step procedure. In the first step, the phosphonate monoester S32.2 is transformed into the chloro analog $RP(O)(OR^1)Cl$ by
5 reaction with thionyl chloride or oxalyl chloride and the like, as described in Organic Phosphorus Compounds, G. M. Kosolapoff, L. Maeir, eds, Wiley, 1976, p. 17, and the thus-obtained product $RP(O)(OR^1)Cl$ is then reacted with the hydroxy compound R^1OH , in the presence of a base such as triethylamine, to afford the phosphonate diester S32.1.

10 A phosphonic acid R-link- $P(O)(OH)_2$ is transformed into a phosphonate monoester $RP(O)(OR^1)(OH)$ (Scheme 32, Reaction 5) by means of the methods described above of for the preparation of the phosphonate diester R-link- $P(O)(OR^1)_2$ S32.1, except that only one molar proportion of the component R^1OH or R^1Br is employed. Dialkyl phosphonates may be prepared according to
15 the methods of: Quast et al (1974) *Synthesis* 490; Stowell et al (1990) *Tetrahedron Lett.* 3261; US 5663159.

A phosphonic acid R-link- $P(O)(OH)_2$ S32.3 is transformed into a phosphonate diester R-link- $P(O)(OR^1)_2$ S32.1 (Scheme 32, Reaction 6) by a coupling reaction with the hydroxy compound R^1OH , in the presence of a
20 coupling agent such as Aldrithiol-2 (Aldrich) and triphenylphosphine. The reaction is conducted in a basic solvent such as pyridine. Alternatively, phosphonic acids S32.3 are transformed into phosphonic esters S32.1 in which R^1 is aryl, by means of a coupling reaction employing, for example, dicyclohexylcarbodiimide in pyridine at ca 70 °C. Alternatively, phosphonic
25 acids S32.3 are transformed into phosphonic esters S32.1 in which R^1 is alkenyl, by means of an alkylation reaction. The phosphonic acid is reacted with the alkenyl bromide R^1Br in a polar organic solvent such as acetonitrile solution at reflux temperature, the presence of a base such as cesium carbonate, to afford the phosphonic ester S32.1.

Preparation of phosphonate carbamates.

Phosphonate esters may contain a carbamate linkage. The preparation of carbamates is described in Comprehensive Organic Functional Group Transformations, A. R. Katritzky, ed., Pergamon, 1995, Vol. 6, p. 416ff, and in Organic Functional Group Preparations, by S. R. Sandler and W. Karo, Academic Press, 1986, p. 260ff. The carbamoyl group may be formed by reaction of a hydroxy group according to the methods known in the art, including the teachings of Ellis, US 2002/0103378 A1 and Hajima, US 6018049.

Scheme 33 illustrates various methods by which the carbamate linkage is synthesized. As shown in Scheme 33, in the general reaction generating carbamates, an alcohol S33.1, is converted into the activated derivative S33.2 in which Lv is a leaving group such as halo, imidazolyl, benztriazolyl and the like,

as described herein. The activated derivative S33.2 is then reacted with an amine S33.3, to afford the carbamate product S33.4. Examples 1 – 7 in Scheme 33 depict methods by which the general reaction is effected. Examples 8 - 10 illustrate alternative methods for the preparation of carbamates.

5 Scheme 33, Example 1 illustrates the preparation of carbamates employing a chloroformyl derivative of the alcohol S33.5. In this procedure, the alcohol S33.5 is reacted with phosgene, in an inert solvent such as toluene, at about 0 °C, as described in Org. Syn. Coll. Vol. 3, 167, 1965, or with an equivalent reagent such as trichloromethoxy chloroformate, as described in Org.
10 Syn. Coll. Vol. 6, 715, 1988, to afford the chloroformate S33.6. The latter compound is then reacted with the amine component S33.3, in the presence of an organic or inorganic base, to afford the carbamate S33.7. For example, the chloroformyl compound S33.6 is reacted with the amine S33.3 in a water-miscible solvent such as tetrahydrofuran, in the presence of aqueous sodium
15 hydroxide, as described in Org. Syn. Coll. Vol. 3, 167, 1965, to yield the carbamate S33.7. Alternatively, the reaction is performed in dichloromethane in the presence of an organic base such as diisopropylethylamine or dimethylaminopyridine.

 Scheme 33, Example 2 depicts the reaction of the chloroformate
20 compound S33.6 with imidazole to produce the imidazolide S33.8. The imidazolide product is then reacted with the amine S33.3 to yield the carbamate S33.7. The preparation of the imidazolide is performed in an aprotic solvent such as dichloromethane at 0°, and the preparation of the carbamate is conducted in a similar solvent at ambient temperature, optionally in the presence of a base such
25 as dimethylaminopyridine, as described in *J. Med. Chem.*, 1989, 32, 357.

 Scheme 33 Example 3, depicts the reaction of the chloroformate S33.6 with an activated hydroxyl compound R"OH, to yield the mixed carbonate ester S33.10. The reaction is conducted in an inert organic solvent such as ether or dichloromethane, in the presence of a base such as dicyclohexylamine or
30 triethylamine. The hydroxyl component R"OH is selected from the group of compounds S33.19 - S33.24 shown in Scheme 33, and similar compounds. For example, if the component R"OH is hydroxybenztriazole S33.19, N-

hydroxysuccinimide S33.20, or pentachlorophenol, S33.21, the mixed carbonate S33.10 is obtained by the reaction of the chloroformate with the hydroxyl compound in an ethereal solvent in the presence of dicyclohexylamine, as described in *Can. J. Chem.*, 1982, 60, 976. A similar reaction in which the
5 component R"OH is pentafluorophenol S33.22 or 2-hydroxypyridine S33.23 is performed in an ethereal solvent in the presence of triethylamine, as described in *Syn.*, 1986, 303, and *Chem. Ber.* 118, 468, 1985.

Scheme 33 Example 4 illustrates the preparation of carbamates in which an alkyloxycarbonylimidazole S33.8 is employed. In this procedure, an alcohol
10 S33.5 is reacted with an equimolar amount of carbonyl diimidazole S33.11 to prepare the intermediate S33.8. The reaction is conducted in an aprotic organic solvent such as dichloromethane or tetrahydrofuran. The acyloxyimidazole S33.8 is then reacted with an equimolar amount of the amine R'NH₂ to afford the carbamate S33.7. The reaction is performed in an aprotic organic solvent such as
15 dichloromethane, as described in *Tet. Lett.*, 42, 2001, 5227, to afford the carbamate S33.7.

Scheme 33, Example 5 illustrates the preparation of carbamates by means of an intermediate alkoxycarbonylbenztriazole S33.13. In this procedure, an alcohol ROH is reacted at ambient temperature with an equimolar amount of
20 benztriazole carbonyl chloride S33.12, to afford the alkoxycarbonyl product S33.13. The reaction is performed in an organic solvent such as benzene or toluene, in the presence of a tertiary organic amine such as triethylamine, as described in *Synthesis.*, 1977, 704. The product is then reacted with the amine R'NH₂ to afford the carbamate S33.7. The reaction is conducted in toluene or
25 ethanol, at from ambient temperature to about 80 °C as described in *Synthesis.*, 1977, 704.

Scheme 33, Example 6 illustrates the preparation of carbamates in which a carbonate (R"O)₂CO, S33.14, is reacted with an alcohol S33.5 to afford the intermediate alkyloxycarbonyl intermediate S33.15. The latter reagent is then
30 reacted with the amine R'NH₂ to afford the carbamate S33.7. The procedure in which the reagent S33.15 is derived from hydroxybenztriazole S33.19 is described in *Synthesis*, 1993, 908; the procedure in which the reagent S33.15 is

derived from N-hydroxysuccinimide S33.20 is described in *Tet. Lett.*, 1992, 2781; the procedure in which the reagent S33.15 is derived from 2-hydroxypyridine S33.23 is described in *Tet. Lett.*, 1991, 4251; the procedure in which the reagent S33.15 is derived from 4-nitrophenol S33.24 is described in
5 *Synthesis*, 1993, 103. The reaction between equimolar amounts of the alcohol ROH and the carbonate S33.14 is conducted in an inert organic solvent at ambient temperature.

Scheme 33, Example 7 illustrates the preparation of carbamates from alkoxycarbonyl azides S33.16. In this procedure, an alkyl chloroformate S33.6 is
10 reacted with an azide, for example sodium azide, to afford the alkoxycarbonyl azide S33.16. The latter compound is then reacted with an equimolar amount of the amine R'NH₂ to afford the carbamate S33.7. The reaction is conducted at ambient temperature in a polar aprotic solvent such as dimethylsulfoxide, for example as described in *Synthesis*, 1982, 404.

15 Scheme 33, Example 8 illustrates the preparation of carbamates by means of the reaction between an alcohol ROH and the chloroformyl derivative of an amine S33.17. In this procedure, which is described in Synthetic Organic Chemistry, R. B. Wagner, H. D. Zook, Wiley, 1953, p. 647, the reactants are combined at ambient temperature in an aprotic solvent such as acetonitrile, in the
20 presence of a base such as triethylamine, to afford the carbamate S33.7.

Scheme 33, Example 9 illustrates the preparation of carbamates by means of the reaction between an alcohol ROH and an isocyanate S33.18. In this procedure, which is described in Synthetic Organic Chemistry, R. B. Wagner, H. D. Zook, Wiley, 1953, p. 645, the reactants are combined at ambient temperature
25 in an aprotic solvent such as ether or dichloromethane and the like, to afford the carbamate S33.7.

Scheme 33, Example 10 illustrates the preparation of carbamates by means of the reaction between an alcohol ROH and an amine R'NH₂. In this procedure, which is described in *Chem. Lett.* 1972, 373, the reactants are
30 combined at ambient temperature in an aprotic organic solvent such as tetrahydrofuran, in the presence of a tertiary base such as triethylamine, and

selenium. Carbon monoxide is passed through the solution and the reaction proceeds to afford the carbamate S33.7.

5. A number of methods are available for the conversion of phosphonic acids into amidates and esters. In one group of methods, the phosphonic acid is

either converted into an isolated activated intermediate such as a phosphoryl chloride, or the phosphonic acid is activated in situ for reaction with an amine or a hydroxy compound.

The conversion of phosphonic acids into phosphoryl chlorides is accomplished by reaction with thionyl chloride, for example as described in *J. Gen. Chem. USSR*, 1983, 53, 480, *Zh. Obschei Khim.*, 1958, 28, 1063, or *J. Org. Chem.*, 1994, 59, 6144, or by reaction with oxalyl chloride, as described in *J. Am. Chem. Soc.*, 1994, 116, 3251, or *J. Org. Chem.*, 1994, 59, 6144, or by reaction with phosphorus pentachloride, as described in *J. Org. Chem.*, 2001, 66, 329, or in *J. Med. Chem.*, 1995, 38, 1372. The resultant phosphoryl chlorides are then reacted with amines or hydroxy compounds in the presence of a base to afford the amidate or ester products.

Phosphonic acids are converted into activated imidazolyl derivatives by reaction with carbonyl diimidazole, as described in *J. Chem. Soc., Chem. Comm.* (1991) 312, or *Nucleosides & Nucleotides* (2000) 19:1885. Activated sulfonyloxy derivatives are obtained by the reaction of phosphonic acids with trichloromethylsulfonyl chloride or with triisopropylbenzenesulfonyl chloride, as described in *Tet. Lett.* (1996) 7857, or *Bioorg. Med. Chem. Lett.* (1998) 8:663. The activated sulfonyloxy derivatives are then reacted with amines or hydroxy compounds to afford amidates or esters.

Alternatively, the phosphonic acid and the amine or hydroxy reactant are combined in the presence of a diimide coupling agent. The preparation of phosphonic amidates and esters by means of coupling reactions in the presence of dicyclohexyl carbodiimide is described, for example, in *J. Chem. Soc., Chem. Comm.* (1991) 312 or *Coll. Czech. Chem. Comm.* (1987) 52:2792. The use of ethyl dimethylaminopropyl carbodiimide for activation and coupling of phosphonic acids is described in *Tet. Lett.*, (2001) 42:8841, or *Nucleosides & Nucleotides* (2000) 19:1885.

A number of additional coupling reagents have been described for the preparation of amidates and esters from phosphonic acids. The agents include Aldrithiol-2, and PYBOP and BOP, as described in *J. Org. Chem.*, 1995, 60, 5214, and *J. Med. Chem.* (1997) 40:3842, mesitylene-2-sulfonyl-3-nitro-1,2,4-

triazole (MSNT), as described in *J. Med. Chem.* (1996) 39:4958, diphenylphosphoryl azide, as described in *J. Org. Chem.* (1984) 49:1158, 1-(2,4,6-triisopropylbenzenesulfonyl-3-nitro-1,2,4-triazole (TPSNT) as described in *Bioorg. Med. Chem. Lett.* (1998) 8:1013,

- 5 bromotris(dimethylamino)phosphonium hexafluorophosphate (BroP), as described in *Tet. Lett.*, (1996) 37:3997, 2-chloro-5,5-dimethyl-2-oxo-1,3,2-dioxaphosphinane, as described in *Nucleosides Nucleotides* 1995, 14, 871, and diphenyl chlorophosphate, as described in *J. Med. Chem.*, 1988, 31, 1305.

- Phosphonic acids are converted into amidates and esters by means of the
10 Mitsunobu reaction, in which the phosphonic acid and the amine or hydroxy reactant are combined in the presence of a triaryl phosphine and a dialkyl azodicarboxylate. The procedure is described in *Org. Lett.*, 2001, 3, 643, or *J. Med. Chem.*, 1997, 40, 3842.

- Phosphonic esters are also obtained by the reaction between phosphonic
15 acids and halo compounds, in the presence of a suitable base. The method is described, for example, in *Anal. Chem.*, 1987, 59, 1056, or *J. Chem. Soc. Perkin Trans., I*, 1993, 19, 2303, or *J. Med. Chem.*, 1995, 38, 1372, or *Tet. Lett.*, 2002, 43, 1161.

- Schemes 34-37 illustrate the conversion of phosphonate esters and
20 phosphonic acids into carboalkoxy-substituted phosphonbisamidates (Scheme 34), phosphonamidates (Scheme 35), phosphonate monoesters (Scheme 36) and phosphonate diesters, (Scheme 37). Scheme 38 illustrates synthesis of gem-dialkyl amino phosphonate reagents.

- Scheme 34 illustrates various methods for the conversion of phosphonate
25 diesters S34.1 into phosphonbisamidates S34.5. The diester S34.1, prepared as described previously, is hydrolyzed, either to the monoester S34.2 or to the phosphonic acid S34.6. The methods employed for these transformations are described above. The monoester S34.2 is converted into the monoamidate S34.3 by reaction with an aminoester S34.9, in which the group R² is H or alkyl; the
30 group R^{4b} is a divalent alkylene moiety such as, for example, CHCH₃, CHCH₂CH₃, CH(CH(CH₃)₂), CH(CH₂Ph), and the like, or a side chain group present in natural or modified aminoacids; and the group R^{5b} is C₁-C₁₂ alkyl,

such as methyl, ethyl, propyl, isopropyl, or isobutyl; C₆-C₂₀ aryl, such as phenyl or substituted phenyl; or C₆-C₂₀ arylalkyl, such as benzyl or benzyldryl. The reactants are combined in the presence of a coupling agent such as a carbodiimide, for example dicyclohexyl carbodiimide, as described in *J. Am. Chem. Soc.*, (1957) 79:3575, optionally in the presence of an activating agent such as hydroxybenztriazole, to yield the amidate product S34.3. The amidate-forming reaction is also effected in the presence of coupling agents such as BOP, as described in *J. Org. Chem.* (1995) 60:5214, Aldrithiol, PYBOP and similar coupling agents used for the preparation of amides and esters. Alternatively, the reactants S34.2 and S34.9 are transformed into the monoamidate S34.3 by means of a Mitsunobu reaction. The preparation of amidates by means of the Mitsunobu reaction is described in *J. Med. Chem.* (1995) 38:2742. Equimolar amounts of the reactants are combined in an inert solvent such as tetrahydrofuran in the presence of a triaryl phosphine and a dialkyl azodicarboxylate. The thus-obtained monoamidate ester S34.3 is then transformed into amidate phosphonic acid S34.4. The conditions used for the hydrolysis reaction depend on the nature of the R¹ group, as described previously. The phosphonic acid amidate S34.4 is then reacted with an aminoester S34.9, as described above, to yield the bisamidate product S34.5, in which the amino substituents are the same or different. Alternatively, the phosphonic acid S34.6 may be treated with two different amino ester reagents simultaneously, *i.e.* S34.9 where R², R^{4b} or R^{5b} are different. The resulting mixture of bisamidate products S34.5 may then be separable, *e.g.* by chromatography.

Scheme 34

5

An example of this procedure is shown in Scheme 34, Example 1. In this procedure, a dibenzyl phosphonate S34.14 is reacted with diazabicyclooctane (DABCO) in toluene at reflux, as described in *J. Org. Chem.*, 1995, 60, 2946, to afford the monobenzyl phosphonate S34.15. The product is then reacted with equimolar amounts of ethyl alaninate S34.16 and dicyclohexyl carbodiimide in pyridine, to yield the amidate product S34.17. The benzyl group is then removed, for example by hydrogenolysis over a palladium catalyst, to give the monoacid product S34.18 which may be unstable according to *J. Med. Chem.* (1997) 40(23):3842. This compound S34.18 is then reacted in a Mitsunobu reaction with ethyl leucinate S34.19, triphenyl phosphine and

15

diethylazodicarboxylate, as described in *J. Med. Chem.*, 1995, 38, 2742, to produce the bisamidate product S34.20.

Using the above procedures, but employing in place of ethyl leucinate S34.19 or ethyl alaninate S34.16, different aminoesters S34.9, the corresponding products S34.5 are obtained.

Alternatively, the phosphonic acid S34.6 is converted into the bisamidate S34.5 by use of the coupling reactions described above. The reaction is performed in one step, in which case the nitrogen-related substituents present in the product S34.5 are the same, or in two steps, in which case the nitrogen-related substituents can be different.

An example of the method is shown in Scheme 34, Example 2. In this procedure, a phosphonic acid S34.6 is reacted in pyridine solution with excess ethyl phenylalaninate S34.21 and dicyclohexylcarbodiimide, for example as described in *J. Chem. Soc., Chem. Comm.*, 1991, 1063, to give the bisamidate product S34.22.

Using the above procedures, but employing, in place of ethyl phenylalaninate, different aminoesters S34.9, the corresponding products S34.5 are obtained.

As a further alternative, the phosphonic acid S34.6 is converted into the mono or bis-activated derivative S34.7, in which Lv is a leaving group such as chloro, imidazolyl, triisopropylbenzenesulfonyloxy etc. The conversion of phosphonic acids into chlorides S34.7 (Lv = Cl) is effected by reaction with thionyl chloride or oxalyl chloride and the like, as described in Organic Phosphorus Compounds, G. M. Kosolapoff, L. Maeir, eds, Wiley, 1976, p. 17. The conversion of phosphonic acids into monoimidazolides S34.7 (Lv = imidazolyl) is described in *J. Med. Chem.*, 2002, 45, 1284 and in *J. Chem. Soc. Chem. Comm.*, 1991, 312. Alternatively, the phosphonic acid is activated by reaction with triisopropylbenzenesulfonyl chloride, as described in *Nucleosides and Nucleotides*, 2000, 10, 1885. The activated product is then reacted with the aminoester S34.9, in the presence of a base, to give the bisamidate S34.5. The reaction is performed in one step, in which case the nitrogen substituents present

in the product S34.5 are the same, or in two steps, via the intermediate S34.11, in which case the nitrogen substituents can be different.

Examples of these methods are shown in Scheme 34, Examples 3 and 5. In the procedure illustrated in Scheme 34, Example 3, a phosphonic acid S34.6 is
5 reacted with ten molar equivalents of thionyl chloride, as described in *Zh. Obschei Khim.*, 1958, 28, 1063, to give the dichloro compound S34.23. The product is then reacted at reflux temperature in a polar aprotic solvent such as acetonitrile, and in the presence of a base such as triethylamine, with butyl serinate S34.24 to afford the bisamidate product S34.25.

10 Using the above procedures, but employing, in place of butyl serinate S34.24, different aminoesters S34.9, the corresponding products S34.5 are obtained.

In the procedure illustrated in Scheme 34, Example 5, the phosphonic acid S34.6 is reacted, as described in *J. Chem. Soc. Chem. Comm.*, 1991, 312,
15 with carbonyl diimidazole to give the imidazolide S34.S32. The product is then reacted in acetonitrile solution at ambient temperature, with one molar equivalent of ethyl alaninate S34.33 to yield the monodisplacement product S34.S34. The latter compound is then reacted with carbonyl diimidazole to produce the activated intermediate S34.35, and the product is then reacted, under
20 the same conditions, with ethyl N-methylalaninate S34.33a to give the bisamidate product S34.36.

Using the above procedures, but employing, in place of ethyl alaninate S34.33 or ethyl N-methylalaninate S34.33a, different aminoesters S34.9, the corresponding products S34.5 are obtained.

25 The intermediate monoamidate S34.3 is also prepared from the monoester S34.2 by first converting the monoester into the activated derivative S34.8 in which Lv is a leaving group such as halo, imidazolyl etc, using the procedures described above. The product S34.8 is then reacted with an aminoester S34.9 in the presence of a base such as pyridine, to give an
30 intermediate monoamidate product S34.3. The latter compound is then converted, by removal of the R¹ group and coupling of the product with the aminoester S34.9, as described above, into the bisamidate S34.5.

An example of this procedure, in which the phosphonic acid is activated by conversion to the chloro derivative S34.26, is shown in Scheme 34, Example 4. In this procedure, the phosphonic monobenzyl ester S34.15 is reacted, in dichloromethane, with thionyl chloride, as described in *Tet. Letters.*, 1994, 35, 4097, to afford the phosphoryl chloride S34.26. The product is then reacted in acetonitrile solution at ambient temperature with one molar equivalent of ethyl 3-amino-2-methylpropionate S34.27 to yield the monoamidate product S34.28. The latter compound is hydrogenated in ethylacetate over a 5% palladium on carbon catalyst to produce the monoacid product S34.29. The product is subjected to a Mitsunobu coupling procedure, with equimolar amounts of butyl alaninate S34.30, triphenyl phosphine, diethylazodicarboxylate and triethylamine in tetrahydrofuran, to give the bisamidate product S34.31.

Using the above procedures, but employing, in place of ethyl 3-amino-2-methylpropionate S34.27 or butyl alaninate S34.30, different aminoesters S34.9, the corresponding products S34.5 are obtained.

The activated phosphonic acid derivative S34.7 is also converted into the bisamidate S34.5 via the diamino compound S34.10. The conversion of activated phosphonic acid derivatives such as phosphoryl chlorides into the corresponding amino analogs S34.10, by reaction with ammonia, is described in Organic Phosphorus Compounds, G. M. Kosolapoff, L. Maeir, eds, Wiley, 1976. The bisamino compound S34.10 is then reacted at elevated temperature with a haloester S34.12 (Hal = halogen, *i.e.* F, Cl, Br, I), in a polar organic solvent such as dimethylformamide, in the presence of a base such as 4, 4-dimethylaminopyridine (DMAP) or potassium carbonate, to yield the bisamidate S34.5. Alternatively, S34.6 may be treated with two different amino ester reagents simulataneously, *i.e.* S34.12 where R^{4b} or R^{5b} are different. The resulting mixture of bisamidate products S34.5 may then be separable, *e.g.* by chromatography.

An example of this procedure is shown in Scheme 34, Example 6. In this method, a dichlorophosphonate S34.23 is reacted with ammonia to afford the diamide S34.37. The reaction is performed in aqueous, aqueous alcoholic or alcoholic solution, at reflux temperature. The resulting diamino compound is

then reacted with two molar equivalents of ethyl 2-bromo-3-methylbutyrate S34.38, in a polar organic solvent such as N-methylpyrrolidinone at ca. 150 °C, in the presence of a base such as potassium carbonate, and optionally in the presence of a catalytic amount of potassium iodide, to afford the bisamidate product S34.39.

Using the above procedures, but employing, in place of ethyl 2-bromo-3-methylbutyrate S34.38, different haloesters S34.12 the corresponding products S34.5 are obtained.

The procedures shown in Scheme 34 are also applicable to the preparation of bisamidates in which the aminoester moiety incorporates different functional groups. Scheme 34, Example 7 illustrates the preparation of bisamidates derived from tyrosine. In this procedure, the monoimidazolid S34.32 is reacted with propyl tyrosinate S34.40, as described in Example 5, to yield the monoamidate S34.41. The product is reacted with carbonyl diimidazole to give the imidazolid S34.42, and this material is reacted with a further molar equivalent of propyl tyrosinate to produce the bisamidate product S34.43.

Using the above procedures, but employing, in place of propyl tyrosinate S34.40, different aminoesters S34.9, the corresponding products S34.5 are obtained. The aminoesters employed in the two stages of the above procedure can be the same or different, so that bisamidates with the same or different amino substituents are prepared.

Scheme 35 illustrates methods for the preparation of phosphonate monoamidates.

In one procedure, a phosphonate monoester S34.1 is converted, as described in Scheme 34, into the activated derivative S34.8. This compound is then reacted, as described above, with an aminoester S34.9, in the presence of a base, to afford the monoamidate product S35.1.

The procedure is illustrated in Scheme 35, Example 1. In this method, a monophenyl phosphonate S35.7 is reacted with, for example, thionyl chloride, as described in *J. Gen. Chem. USSR.*, 1983, 32, 367, to give the chloro product S35.8. The product is then reacted, as described in Scheme 34, with ethyl alaninate S3, to yield the amidate S35.10.

Using the above procedures, but employing, in place of ethyl alaninate S35.9, different aminoesters S34.9, the corresponding products S35.1 are obtained.

Alternatively, the phosphonate monoester S34.1 is coupled, as described in Scheme 34, with an aminoester S34.9 to produce the amidate S35.1. If necessary, the R¹ substituent is then altered, by initial cleavage to afford the phosphonic acid S35.2. The procedures for this transformation depend on the nature of the R¹ group, and are described above. The phosphonic acid is then transformed into the ester amidate product S35.3, by reaction with the hydroxy compound R³OH, in which the group R³ is aryl, heterocycle, alkyl, cycloalkyl, haloalkyl etc, using the same coupling procedures (carbodiimide, Aldrich 12, PYBOP, Mitsunobu reaction etc) described in Scheme 34 for the coupling of amines and phosphonic acids.

Scheme 34 Example 4

Scheme 34 Example 5

Scheme 34 Example 6

Scheme 34 Example 7

Examples of this method are shown in Scheme 35, Examples 2 and 3. In the sequence shown in Example 2, a monobenzyl phosphonate S35.11 is transformed by reaction with ethyl alaninate, using one of the methods described above, into the monoamidate S35.12. The benzyl group is then removed by catalytic hydrogenation in ethylacetate solution over a 5% palladium on carbon catalyst, to afford the phosphonic acid amidate S35.13. The product is then reacted in dichloromethane solution at ambient temperature with equimolar amounts of 1-(dimethylaminopropyl)-3-ethylcarbodiimide and trifluoroethanol S35.14, for example as described in *Tet. Lett.*, 2001, 42, 8841, to yield the amidate ester S35.15.

In the sequence shown in Scheme 35, Example 3, the monoamidate S35.13 is coupled, in tetrahydrofuran solution at ambient temperature, with equimolar amounts of dicyclohexyl carbodiimide and 4-hydroxy-N-methylpiperidine S35.16, to produce the amidate ester product S35.17.

Using the above procedures, but employing, in place of the ethyl alaninate product S35.12 different monoacids S35.2, and in place of

trifluoroethanol S35.14 or 4-hydroxy-N-methylpiperidine S35.16, different hydroxy compounds R^3OH , the corresponding products S35.3 are obtained.

Alternatively, the activated phosphonate ester S34.8 is reacted with ammonia to yield the amidate S35.4. The product is then reacted, as described in Scheme 34, with a haloester S35.5, in the presence of a base, to produce the amidate product S35.6. If appropriate, the nature of the R^1 group is changed, using the procedures described above, to give the product S35.3. The method is illustrated in Scheme 35, Example 4. In this sequence, the monophenyl phosphoryl chloride S35.18 is reacted, as described in Scheme 34, with ammonia, to yield the amino product S35.19. This material is then reacted in N-methylpyrrolidinone solution at 170° with butyl 2-bromo-3-phenylpropionate S35.20 and potassium carbonate, to afford the amidate product S35.21.

Using these procedures, but employing, in place of butyl 2-bromo-3-phenylpropionate S35.20, different haloesters S35.5, the corresponding products S35.6 are obtained.

The monoamidate products S35.3 are also prepared from the doubly activated phosphonate derivatives S34.7. In this procedure, examples of which are described in *Synlett.*, 1998, 1, 73, the intermediate S34.7 is reacted with a limited amount of the aminoester S34.9 to give the mono-displacement product S34.11. The latter compound is then reacted with the hydroxy compound R^3OH in a polar organic solvent such as dimethylformamide, in the presence of a base such as diisopropylethylamine, to yield the monoamidate ester S35.3.

The method is illustrated in Scheme 35, Example 5. In this method, the phosphoryl dichloride S35.22 is reacted in dichloromethane solution with one molar equivalent of ethyl N-methyl tyrosinate S35.23 and dimethylaminopyridine, to generate the monoamidate S35.24. The product is then reacted with phenol S35.25 in dimethylformamide containing potassium carbonate, to yield the ester amidate product S35.26.

Using these procedures, but employing, in place of ethyl N-methyl tyrosinate S35.23 or phenol S35.25, the aminoesters 34.9 and/or the hydroxy compounds R^3OH , the corresponding products S35.3 are obtained.

5 Scheme 36 illustrates methods for the preparation of carboalkoxy-substituted phosphonate diesters in which one of the ester groups incorporates a carboalkoxy substituent.

In one procedure, a phosphonate monoester S34.1, prepared as described above, is coupled, using one of the methods described above, with a hydroxyester S36.1, in which the groups R^{4b} and R^{5b} are as described in Scheme 34. For example, equimolar amounts of the reactants are coupled in the presence of a carbodiimide such as dicyclohexyl carbodiimide, as described in *Aust. J. Chem.*, 1963, 609, optionally in the presence of dimethylaminopyridine, as described in *Tet.*, 1999, 55, 12997. The reaction is conducted in an inert solvent at ambient temperature.

The procedure is illustrated in Scheme 36, Example 1. In this method, a monophenyl phosphonate S36.9 is coupled, in dichloromethane solution in the presence of dicyclohexyl carbodiimide, with ethyl 3-hydroxy-2-methylpropionate S36.10 to yield the phosphonate mixed diester S36.11.

5 Using this procedure, but employing, in place of ethyl 3-hydroxy-2-methylpropionate S36.10, different hydroxyesters S33.1, the corresponding products S33.2 are obtained.

The conversion of a phosphonate monoester S34.1 into a mixed diester S36.2 is also accomplished by means of a Mitsunobu coupling reaction with the hydroxyester S36.1, as described in *Org. Lett.*, 2001, 643. In this method, the reactants 34.1 and S36.1 are combined in a polar solvent such as tetrahydrofuran, in the presence of a triarylphosphine and a dialkyl azodicarboxylate, to give the mixed diester S36.2. The R¹ substituent is varied by cleavage, using the methods described previously, to afford the monoacid product S36.3. The product is then
10 coupled, for example using methods described above, with the hydroxy compound R³OH, to give the diester product S36.4.

The procedure is illustrated in Scheme 36, Example 2. In this method, a monoallyl phosphonate S36.12 is coupled in tetrahydrofuran solution, in the presence of triphenylphosphine and diethylazodicarboxylate, with ethyl lactate
20 S36.13 to give the mixed diester S36.14. The product is reacted with tris(triphenylphosphine) rhodium chloride (Wilkinson catalyst) in acetonitrile, as described previously, to remove the allyl group and produce the monoacid product S36.15. The latter compound is then coupled, in pyridine solution at ambient temperature, in the presence of dicyclohexyl carbodiimide, with one
25 molar equivalent of 3-hydroxypyridine S36.16 to yield the mixed diester S36.17.

Using the above procedures, but employing, in place of the ethyl lactate S36.13 or 3-hydroxypyridine, a different hydroxyester S36.1 and/or a different hydroxy compound R³OH, the corresponding products S36.4 are obtained.

The mixed diesters S36.2 are also obtained from the monoesters S34.1
30 via the intermediacy of the activated monoesters S36.5. In this procedure, the monoester S34.1 is converted into the activated compound S36.5 by reaction with, for example, phosphorus pentachloride, as described in *J. Org. Chem.*,

2001, 66, 329, or with thionyl chloride or oxalyl chloride ($L_v = Cl$), or with triisopropylbenzenesulfonyl chloride in pyridine, as described in *Nucleosides and Nucleotides*, 2000, 19, 1885, or with carbonyl diimidazole, as described in *J. Med. Chem.*, 2002, 45, 1284. The resultant activated monoester is then reacted
5 with the hydroxyester S36.1, as described above, to yield the mixed diester S36.2.

The procedure is illustrated in Scheme 36, Example 3. In this sequence, a monophenyl phosphonate S36.9 is reacted, in acetonitrile solution at 70 °C, with ten equivalents of thionyl chloride, so as to produce the phosphoryl chloride
10 S36.19. The product is then reacted with ethyl 4-carbamoyl-2-hydroxybutyrate S36.20 in dichloromethane containing triethylamine, to give the mixed diester S36.21.

Using the above procedures, but employing, in place of ethyl 4-carbamoyl-2-hydroxybutyrate S36.20, different hydroxyesters S36.1, the
15 corresponding products S36.2 are obtained.

The mixed phosphonate diesters are also obtained by an alternative route for incorporation of the R^3O group into intermediates S36.3 in which the hydroxyester moiety is already incorporated. In this procedure, the monoacid intermediate S36.3 is converted into the activated derivative S36.6 in which L_v
20 is a leaving group such as chloro, imidazole, and the like, as previously described. The activated intermediate is then reacted with the hydroxy compound R^3OH , in the presence of a base, to yield the mixed diester product S36.4.

The method is illustrated in Scheme 36, Example 4. In this sequence, the
25 phosphonate monoacid S36.22 is reacted with trichloromethanesulfonyl chloride in tetrahydrofuran containing collidine, as described in *J. Med. Chem.*, 1995, 38, 4648, to produce the trichloromethanesulfonyloxy product S36.23. This compound is reacted with 3-(morpholinomethyl)phenol S36.24 in dichloromethane containing triethylamine, to yield the mixed diester product
30 S36.25.

Using the above procedures, but employing, in place of with 3-(morpholinomethyl)phenol S36.24, different alcohols R^3OH , the corresponding products S36.4 are obtained.

The phosphonate esters S36.4 are also obtained by means of alkylation
5 reactions performed on the monoesters S34.1. The reaction between the monoacid S34.1 and the haloester S36.7 is performed in a polar solvent in the presence of a base such as diisopropylethylamine, as described in *Anal. Chem.*, 1987, 59, 1056, or triethylamine, as described in *J. Med. Chem.*, 1995, 38, 1372, or in a non-polar solvent such as benzene, in the presence of 18-crown-6, as
10 described in *Syn. Comm.*, 1995, 25, 3565.

The method is illustrated in Scheme 36, Example 5. In this procedure, the monoacid S36.26 is reacted with ethyl 2-bromo-3-phenylpropionate S36.27 and diisopropylethylamine in dimethylformamide at 80 °C to afford the mixed diester product S36.28.

15 Using the above procedure, but employing, in place of ethyl 2-bromo-3-phenylpropionate S36.27, different haloesters S36.7, the corresponding products S36.4 are obtained.

Scheme 37 illustrates methods for the preparation of phosphonate diesters in which both the ester substituents incorporate carboalkoxy groups.

- 5 The compounds are prepared directly or indirectly from the phosphonic acids S34.6. In one alternative, the phosphonic acid is coupled with the hydroxyester S37.2, using the conditions described previously in Schemes 34-36, such as coupling reactions using dicyclohexyl carbodiimide or similar reagents, or under the conditions of the Mitsunobu reaction, to afford the diester
- 10 product S37.3 in which the ester substituents are identical.

This method is illustrated in Scheme 37, Example 1. In this procedure, the phosphonic acid S34.6 is reacted with three molar equivalents of butyl lactate

S37.5 in the presence of Aldrithiol-2 and triphenyl phosphine in pyridine at ca. 70 °C, to afford the diester S37.6.

Using the above procedure, but employing, in place of butyl lactate S37.5, different hydroxyesters S37.2, the corresponding products S37.3 are
5 obtained.

Alternatively, the diesters S37.3 are obtained by alkylation of the phosphonic acid S34.6 with a haloester S37.1. The alkylation reaction is performed as described in Scheme 36 for the preparation of the esters S36.4.

This method is illustrated in Scheme 37, Example 2. In this procedure,
10 the phosphonic acid S34.6 is reacted with excess ethyl 3-bromo-2-methylpropionate S37.7 and diisopropylethylamine in dimethylformamide at ca. 80 °C, as described in *Anal. Chem.*, 1987, 59, 1056, to produce the diester S37.8.

Using the above procedure, but employing, in place of ethyl 3-bromo-2-methylpropionate S37.7, different haloesters S37.1, the corresponding products
15 S37.3 are obtained.

The diesters S37.3 are also obtained by displacement reactions of activated derivatives S34.7 of the phosphonic acid with the hydroxyesters S37.2. The displacement reaction is performed in a polar solvent in the presence of a suitable base, as described in Scheme 36. The displacement reaction is
20 performed in the presence of an excess of the hydroxyester, to afford the diester product S37.3 in which the ester substituents are identical, or sequentially with limited amounts of different hydroxyesters, to prepare diesters S37.3 in which the ester substituents are different.

The methods are illustrated in Scheme 37, Examples 3 and 4. As shown
25 in Example 3, the phosphoryl dichloride S35.22 is reacted with three molar equivalents of ethyl 3-hydroxy-2-(hydroxymethyl)propionate S37.9 in tetrahydrofuran containing potassium carbonate, to obtain the diester product S37.10.

Using the above procedure, but employing, in place of ethyl 3-hydroxy-
30 2-(hydroxymethyl)propionate S37.9, different hydroxyesters S37.2, the corresponding products S37.3 are obtained.

Scheme 37, Example 4 depicts the displacement reaction between equimolar amounts of the phosphoryl dichloride S35.22 and ethyl 2-methyl-3-hydroxypropionate S37.11, to yield the monoester product S37.12. The reaction is conducted in acetonitrile at 70° in the presence of diisopropylethylamine. The product S37.12 is then reacted, under the same conditions, with one molar equivalent of ethyl lactate S37.13, to give the diester product S37.14.

Using the above procedures, but employing, in place of ethyl 2-methyl-3-hydroxypropionate S37.11 and ethyl lactate S37.13, sequential reactions with different hydroxyesters S37.2, the corresponding products S37.3 are obtained.

- 5 2,2-Dimethyl-2-aminoethylphosphonic acid intermediates can be prepared by the route in Scheme 5. Condensation of 2-methyl-2-propanesulfonamide with acetone give sulfinyl imine S38.11 (*J. Org. Chem.* 1999, 64, 12). Addition of dimethyl methylphosphonate lithium to S38.11 afford S38.12. Acidic methanolysis of S38.12 provide amine S38.13. Protection
- 10 of amine with Cbz group and removal of methyl groups yield phosphonic acid

S38.14, which can be converted to desired S38.15 (Scheme 38a) using methods reported earlier on. An alternative synthesis of compound S38.14 is also shown in Scheme 38b. Commercially available 2-amino-2-methyl-1-propanol is converted to aziridines S38.16 according to literature methods (*J. Org. Chem.* 1992, 57, 5813; *Syn. Lett.* 1997, 8, 893). Aziridine opening with phosphite give S38.17 (*Tetrahedron Lett.* 1980, 21, 1623). Reprotection) of S38.17 affords S38.14.

The invention will now be illustrated by the following non-limiting Examples.

15

Example 1. Synthesis of Representative Compounds of Formula 1

- 5 Representative compounds of the invention can be prepared as illustrated above. Dehydroepiandrosterone (purchased from a supplier such as Aldrich), 16-α-bromodehydroepiandrosterone, or 16-β-bromodehydroepiandrosterone (purchased from a supplier such as Steraloids) can be treated with bases such as, but not limited to, Cs₂CO₃ or NaH, in an appropriate solvents such as, but not
- 10 limited to, THF or DMF, in the presence of an alkylating agent of general structure 1.3. Note that X is a leaving group, preferably in this case trifluoromethanesulfonate, but other leaving groups may be used and include bromide, iodide, chloride, *p*-toluenesulfonate, methanesulfonate, among others. The phosphonate esters of the resulting alkylated product 1.4 can then be
- 15 converted into the intended final phosphonate functionality.

- For instance, dehydroepiandrosterone can be treated in anhydrous THF at
- 20 0 °C with NaH. When bubbling ceases, diethyl phosphonomethyltriflate (prepared according to *Tetrahedron Lett.* 1986, 27, 1477) is added yielding intermediate 1.5. The phosphonate esters of 1.5 are then converted into the final desired functionality.

Example 2. Synthesis of Representative Compounds of Formula 2

- 5 Representative compounds of the invention can be prepared as illustrated above. Intermediates 2.2 are prepared according to the methods described in US 6,194,398 and any literature cited therein. The phosphonate ester of 2.2 may be converted to the final desired phosphonic acid functionality. Alternatively, phosphonic acids 2.3 may be formed by cleavage of esters 2.2 by treatment with
- 10 a reagent such as, but not limited to, TMS-bromide in a solvent such as MeCN. Phosphonic acid 2.3 may then be converted to the final desired phosphonic acid functionality.

- 15 For instance, LY-582563, prepared as described in US 6,194,398 is treated with TMS-Br and 2,6-lutidine in MeCN to provide phosphonic acid 2.4. Either LY-582563 or 2.4 may then be converted to the final desired phosphonate derivative.

20

Example 3. Synthesis of Representative Compounds of Formulae 3 and 4

- 5 Representative compounds of the invention can be prepared as illustrated above. L-Fd4C and L-FddC are prepared according to methods in US 5,561,120, US 5,627,160, and US 5,631,239 and any literature references cited therein. Either can be treated with a base such as, but not limited to, NaH or Cs₂CO₃, in a solvent such as, but not limited to, THF or DMF, and an alkylating agent of structure 3.5. In compounds 3.5, X is a leaving group such as, but not limited to, bromide, chloride, iodide, *p*-toluenesulfonate, trifluoromethanesulfonate, or methanesulfonate. It should be noted that cytosine-containing compounds sometimes require protection of the amino group at the 4-position of the base. If necessary, a protecting group may be introduced onto this position before these alkylation reactions are carried out.
- 10
- 15 Introduction of such protecting groups (and their subsequent removal at the end of a synthetic scheme) are processes well known to those skilled in the art of nucleoside and nucleotide synthesis.

For instance, L-FddC is treated with NaH in DMF at 0 °C. When bubbling has ceased, diethyl phosphonomethyltriflate (prepared according to *Tetrahedron Lett.* 1986, 27, 1477) is added. The resulting product 3.8 is isolated by standard chromatographic means. It may be necessary to protect the amino group at the 4-position of the base before this alkylation is carried out. See the note above regarding such protecting groups.

Example 4. Synthesis of Representative Compounds of Formulae 5 and 6

In Example 4, glycol 4.9 (obtained as described in *J. Am. Chem. Soc.* 1972, 94, 3213) is reacted with phenylselenenyl chloride followed by treatment with the respective phosphonate alcohols 4.10 in the presence of silver perchlorate (*J. Org. Chem.* 1991, 56, 2642-2647). Oxidation of the resulting chloride using hydrogen peroxide followed by aminolysis of uracil using triazole, 2-chlorophenyldichlorophosphate, pyridine and ammonia (*Bioorg. Med. Chem. Lett.* 1997, 7, 2567) provides the L-Fd4C phosphonate derivative 4.12. Hydrogenation over 10% Pd/C provides the L-FddC derivative 4.13.

For instance, glycal 4.9 is reacted with phenylselenenyl chloride and then treated with AgClO₄ and diethyl phosphonemethanol (available from Aldrich) providing compound 4.14. Treatment of 4.14 with H₂O₂ and NaHCO₃ in 1,4-dioxane followed by triazole, 2-chlorophenyldichlorophosphate, in pyridine with ammonia yields the fluorocytosine derivative 4.15. Hydrogenation at 1 atm, over 10% Pd/C yields derivative 4.16.

10 Example 5. Synthesis of Representative Compounds of Formula 9

Bases such as but not limited to, thymine, adenine, uracil, 5-halouracils, 5-alkyluracils, guanine, cytosine, 5-halo and alkyl cytosines, 2,6-diaminopurine. Bases requiring protecting groups are to be suitably protected using protecting groups and conditions well known to those skilled in the art.

Representative compounds of the invention can be prepared as illustrated above. Compounds 5.4, prepared as described in WO 00/09531, US 6,395,716, and US 6,444,652, can be converted to glycal 5.11 according to the process reported in *J. Am. Chem. Soc.* 1972, 94, 3213. Glycal 5.11 is then treated with

5 IBr in the presence of alcohol 5.12 to provide intermediate 5.13 (see *J. Org. Chem.* 1991, 56, 2642). The iodide of intermediate 5.13 can be treated with AgOAc to provide acetate 5.14, which can be deacetylated in the presence of catalytic sodium methoxide in methanol. Treatment of this product with DEAD and PPh₃ in the presence of acetic acid, followed by another deprotection with

10 catalytic sodium methoxide in methanol will provide intermediate 5.15, which is representative of Formula 9. The phosphonates of intermediates 5.15 can be converted into other embodiments of the invention according to procedures known to those of skill in the art.

15 For instance, compound 5.8 is converted into glycal 5.16 according to the procedures reported in *J. Am. Chem. Soc.* 1972, 94, 3213. Glycal 5.16 is then treated with IBBr in the presence of diethyl phosphonate to provide intermediate 5.17 (see *J. Org. Chem.* 1991, 56, 2642). Intermediate 5.17 is then

20 treated with AgOAc followed by deprotection with catalytic NaOMe in MeOH to provide 5.18. This compound is then converted into epimer 5.19 by a Mitsunobu reaction with DEAD/PPh₃ and HOAc in THF, followed by a second catalytic NaOMe/MeOH deprotection. At any point in the synthetic sequence

25 where it is appropriate, the phosphonate group may be converted into a phosphonate with the desired substitution.

Example 6. Synthesis of Representative Compounds of Formulae 10 and 11

Representative compounds of the invention can be prepared as illustrated above. The preparation of compounds of structural type 6.6 are described in US 5,565,438, US 5,567,688, and US 5,587,362, and the references cited therein. The compounds are then treated with a limiting amount of NaH in an appropriate solvent such as, but not limited to THF or DMF, and are then treated with an alkylating agent of type 6.7 (X = leaving group such as, but not limited to bromide, chloride, iodide, methanesulfonate, trifluoromethanesulfonate, and *p*-toluenesulfonate). Intermediates 6.8 and 6.9 result as a mixture and can be separated by chromatographic means that are well known to those skilled in the art. It should be noted that if a base requires a protecting group during this alkylation reaction, suitable protecting groups either will have already been installed throughout the synthetic schemes that provided starting materials 6.6 described in the cited patents, or can be installed prior to the alkylation reaction according to methods well known to chemists skilled in the art. If a protecting group had been added, it may be cleaved at this time according to the methods described in the patents cited above or according to any appropriate method known to those skilled in the art. At this point, the phosphonate esters may be converted to the desired final phosphonate functionality.

Clevudine, prepared as described in the patents cited above, is treated in anhydrous THF with NaH at 0 °C. When bubbling ceases, diethyl phosphonomethyltriflate (prepared as in *Tetrahedron Lett.* 1986, 27, 1477) is added. The resulting alkylation products 6.10 and 6.11 are isolated after work-up either using silica gel or reversed-phase chromatography. The phosphonates may then be converted to the final desired products.

Example 7. Synthesis of Representative Compounds of Formula 12

10

B = Base as defined above, with protecting groups, if necessary, as described above

15

Representative compounds of the invention can be prepared as illustrated above. L-Deoxynucleoside 7.12 is synthesized according to literature procedure (see the methods reported by Holy, *Collect. Czech. Chem. Commun.* 1972, 37, 4072). L-Deoxynucleoside 7.12 is then converted into 7.13 through the procedures reported in *J. Am. Chem. Soc.* 1972, 94, 3213 and *J. Org. Chem.* 1991, 56, 2642. Dimethyl phosphonomethanol may be replaced with any alcohol linked to a phosphonate. The double bond of compound 7.13 is then treated with OsO₄ and *N*-methylnmorpholine *N*-oxide to provide the dihydroxylated derivatives 7.14. Triflation of 7.14 results in a mixture of triflates, the desired of which, 7.15, is isolated by the appropriate chromatographic method. The fluoride is installed by treatment of 7.15 with tetra-*n*-butylammonium fluoride (TBAF) in an appropriate solvent, such as THF, yielding the desired intermediate 7.16.

25

A specific compound of Formula 12 can be prepared as follows.

- L-Thymidine 7.17, synthesized by Holy's method, is converted according to the literature procedures cited above to d4 nucleoside derivative
- 5 7.18. Compound 7.18 is then treated with OsO₄ and NMO to give dihydroxylated product 7.19, which is triflated to provide 7.20 (separated by silica gel chromatography from a mixture of its regioisomers and di-triflated material). Compound 7.20 is then treated with TBAF to convert it to the desired compound 7.21. The diethyl phosphonate may now be converted into any group
- 10 that is desired according to methods well known to chemists skilled in the art.

A general scheme that is useful for converting a 3,5-difunctionalized nitrobenzene derivative to an aniline that can be used to prepare a VX-148 analog of the invention is illustrated above.

Example 9. Synthesis of Aniline Intermediate Useful for Preparing VX-148 Analogs of Formula A

Representative compounds of the invention can be prepared as illustrated above. 3-Hydroxy-5-nitro-benzoic acid is heated briefly in thionyl chloride to generate the acid chloride. This is then condensed with *O,N*-dimethyl-hydroxylamine in the presence of a base such as triethylamine to produce the Weinreb amide which, upon reaction with methyl lithium, gives the acetophenone derivative. This intermediate is then treated with a base such as potassium carbonate in a dipolar aprotic solvent such as dimethylformamide, in the presence of an excess of *E*-1,4-dibromobutene. The monobromide is isolated by chromatography and then subjected to treatment with triethylphosphite in a solvent such as toluene (or other Arbuzov reaction conditions: see Engel, R., *Synthesis of carbon-phosphorus bonds*, CRC press, 1988) to generate the desired phosphonate diethyl ester. Thereafter, the carbonyl of the acetophenone is reduced enantioselectively using an appropriate homochiral oxazaborolidine such as those described by Corey (*J. Am. Chem. Soc.*, 1987, 109, 5551), and the resulting alcohol is displaced by azide using a method such as that described by Mitsunobu (*Bull. Chem. Soc. Japan.*, 1971, 44, 3427). The azide is reduced to the amine under Staudinger conditions (*Helv. Chim. Act.*, 1919, 2, 635) and protected as the *t*-butyl carbonate. Finally, the desired aniline is generated by tin (II)-mediated reduction of the nitrobenzene. Using coupling reactions similar to those described in US 6,054,472 and US 6,344,465 will give compounds of Formula A.

Example 12 General Route to Aniline Intermediate Useful For Preparing Representative Compounds of Formula C

3-Nitrobenzaldehyde reacts with a Grignard reagent to introduce a tether bearing a protected alcohol and simultaneously to generate a benzylic alcohol, as shown. The alcohol is displaced by an azide in a manner similar to that described for Example 9. After deprotection, the liberated alcohol is alkylated with diethyl phosphonomethyltriflate (prepared according to *Tetrahedron Lett.* 1986, 27, 1477) using a base such as magnesium tert-butoxide in a solvent such as tetrahydrofuran. Subsequent transformations of the azide and nitro groups proceed in a fashion similar to that described in Example 9. See Batt et al., *Bioorg. Med. Chem. Lett.* 1995, 5, 1549.

Subsequent reduction of the nitro group proceeds in a fashion similar to that described in the scheme in Example 9.

Example 15 Synthesis of Aniline Intermediate Useful for Preparing Compounds of Formula 16

10

Representative compounds of the invention can be prepared as illustrated above. 3-Hydroxy-5-nitro-benzoic acid is heated briefly in acidic methanol to generate the methyl ester. This is then treated with a base such as potassium carbonate in a dipolar aprotic solvent such as dimethylformamide, in the presence of an excess of *E*-1,4-dibromobutene. The monobromide is isolated by chromatography and then subjected to treatment with triethylphosphite in a solvent such as toluene (or other Arbuzov reaction conditions: see Engel, R., Synthesis of carbon-phosphorus bonds, CRC press, 1988) to generate the desired phosphonate diethyl ester. Thereafter, the benzoate ester is saponified and reduced, and the resulting alcohol displaced by azide using a method such as that

20

described by Mitsunobu (*Bull. Chem. Soc. Japan.*, 1971, 44, 3427). The azide is reduced to the amine under Staudinger conditions (*Helv. Chim. Acta*, 1919, 2, 635) and protected as the *t*-butyl carbonate. Finally, the desired aniline is generated by tin (II)-mediated reduction of the nitrobenzene. The aniline is converted to a compound of Formula 16 by the general procedures described in US 6,054,472 and US 6,344,465 as set forth in Example 10.

Example 16 General Route to Representative Compounds of Formula 17

10

Reagents suitable for use in the synthesis of representative compounds of Formula 17 may be made by routes analogous to that shown in Example 10, starting from 2-hydroxy-5-nitro-benzoic acid.

15 Example 17 General Route to Representative Compounds of Formula 18

Representative compounds of Formula 18 can be prepared as illustrated above. The preparation of anilines of formula 17.2 is illustrated in Examples 11-13 above. Anilines of formula 17.2 can be converted to compounds of formula 18 using procedures similar to those described in US 6,054,472 and US 6,344,465.

Example 18. Synthesis of Representative Compounds of Formula 19

Representative compounds of the invention can be prepared as illustrated above. The phosphorus containing BILN-2061 analog 18.2 is synthesized from the parent compound 18.1 by attachment of phosphorus containing moiety to the carboxylic acid group. Compound 18.1, BILN-2061, is obtained by the procedure as described in WO 00/59929. The secondary amine on the thiazole ring is protected with a suitable protecting group, such as Boc group before the formation of ester or amide as shown above. The protected 18.1 is coupled with a phosphorus containing moiety with a hydroxy group by Mitsunobu reaction using triphenylphosphine and diethyl azodicarboxylate, whereas an amide group is formed using amino group containing phosphonate reagent by suitable coupling reagents, such as EDC-HOBt, BOP reagent etc. Deprotection of the coupled product gives the desired phosphonate of type 18.2.

5 For instance, 18.1.1 is protected with Boc group using $(\text{Boc})_2\text{O}$ and triethylamine and then treated with 2-hydroxyethylphosphonic acid diethyl ester 18.7 in the presence of triphenylphosphine and diethyl azodicarboxylate. The resulting ester is treated with trifluoroacetic acid to obtain analog 18.8, in which the linker is ethylene group.

10

Example 19. Synthesis of Representative Compounds of Formula 20

15 Synthesis of phosphonate analog of type 19.3 is illustrated above. The phosphonate containing moiety is introduced to compound 19.1, or its analogs ($R^3 = H, \text{Me}, \text{Et}, i\text{-Pr}$), which are available by the procedure described in WO

00/59929, by reductive amination using the phosphonate reagent 19.9 bearing aldehyde group.

5

For instance, compound 19.1.1 is treated with 2-oxoethyl phosphonic acid diethyl ester 19.10 in the presence of sodium cyanoborohydride and acetic acid to provide compound 19.11, in which the linker is ethylene.

10 Example 20. Synthesis of Representative Compounds of Formula 21

Example 20 illustrates the preparation of compounds of type 20.4. The secondary amine on the thiazole ring and the carboxylic acid are protected with suitable protecting groups. The methoxy group of the quinoline ring at 7-position is then demethylated using boron tribromide. The phosphonate bearing moiety is then introduced on this hydroxy group in a suitable aprotic solvent such as, DMF, by treating with the phosphonate reagent 20.14, in the presence of a suitable organic or inorganic base. In compounds 20.14, X is a leaving group such as, but not limited to, bromide, chloride, iodide, *p*-toluenesulfonate, trifluoromethanesulfonate, or methanesulfonate.

The protecting groups are then removed to obtain the analog of type 20.4.

- For instance, the secondary amino group on the thiazole ring of 20.1 is protected with Boc group using (Boc)₂O and triethylamine, and the carboxylic acid is protected with *t*-butyl group using EDC, DMAP, and *t*-butyl alcohol, which result 20.15 as shown above. After the resulting 20.15 is demethylated by boron tribromide, the alkylation of 20.16 with cesium carbonate and one equivalent of (trifluoromethanesulfonyloxy)methylphosphonic acid diethyl ester 17, followed by deprotection using trifluoroacetic acid gives 20.18, where the linkage is a methylene group as shown above.

Example 21. Synthesis of Representative Compounds of Formula 22

Synthesis of analogs 21.5 of BILN-2061 is illustrated above. Compound 21.19 is synthesized by a procedure described in WO 00/59929 based on methodology by T. Tsuda et al. (*J. Am. Chem. Soc.* 1980, 102, 6381).

Compound 21.20, containing extra carbonyl group with suitable protecting groups, R^4 and R^5 , is synthesized by the procedure described for the synthesis of 21.1 at WO 00/59929 using compound 21.19. The phosphonate group bearing moiety is attached to the carbonyl group of 21.20 by reductive amination. The obtained secondary amine may be converted to the tertiary amine by repeated reductive amination using formaldehyde or acetaldehyde to provide 21.5.2. The carbonyl group of 21.20 is also reduced to the corresponding alcohol and

converted to phenyl carbonate, which is reacted with **21.21** to form compound **21.5.1**, where the linkage is a carbamate. After the phosphonate bearing moiety is attached, the protecting groups, R^4 and R^5 , are removed by suitable methods well know to those skilled in the chemical arts.

5

For instance, compound **21.22**, obtained by the procedure of WO 00/59929, is treated with $(Boc)_2O$ and triethylamine and followed by EDC, DMAP, and *t*-butyl alcohol to provide protected compound **21.23**, as illustrated above. Compound **21.23** is then treated with 2-aminoethylphosphonic acid diethyl ester **21.24** in the presence of sodium cyanoborohydride and acetic acid, which results in the phosphonate bearing compound **21.25** ($R^7 = H$), in which the phosphonate is attached to the structural core through a secondary amine, after deprotection by trifluoroacetic acid. Before deprotection, reductive amination of

the secondary amine in the presence CH_2O generates the tertiary amine, which is converted to 21.25 ($\text{R}^7 = \text{Me}$) bearing a tertiary amine.

Example 22. Synthesis of Representative Compounds of Formula 23

10

Representative compounds of the invention can be prepared as illustrated above. Condensation of commercially available 2-mercapto-ethanol and trimethoxymethane (*J. Org. Chem. USSR (Engl. Transl.)* 1981, 1369-1371) generates heterocycle 22.3. Glycosidation using, for example, trimethylsilyl triflate and the phosphonate substituted alcohol 22.4, provides intermediate 22.5. Oxidation of sulfur to the sulfoxide using monoperoxyphthalic acid, magnesium salt (see US Patent 6,228,860 col. 15 ln. 45-60) followed by a Pummerer rearrangement (see US Patent 6,228,860 col. 16 ln. 25-40) and base introduction (cytosine or 5'-fluoro-cytosine) using conditions as outlined in US Patent 6,228,860 (col. 17 ln. 15-42) provides the desired phosphonate substituted analogs 22.2.

15

20

Specifically, starting with heterocycle 22.3, using the above procedure but using diethyl(hydroxymethyl) phosphonate 22.6, generates 22.7.

- 5 Introduction of cytosine as outlined above provides the desired product 22.8. Using the above procedure, but employing different phosphonate reagents 22.4 in place of 22.6, the corresponding products 22.2 bearing different linking groups are obtained.

10

Example 23. Synthesis of Representative Compounds of Formula 24

15

- Representative compounds of the invention can be prepared by reaction of dOTC analogs of type 23.1 (obtained as described in US 6,228,860 col. 14 line 45 to col. 30 line 50 and references cited therein) with the respective alkylating reagents 23.3. The above scheme shows the preparation of phosphonate linkage to dOTC through the 5' hydroxyl group. Substrate 23.1 (dOTC) is dissolved in a solvent such as, but not limited to, DMF, THF and is

5 treated with a phosphonate reagent bearing a leaving group in the presence of a suitable organic or inorganic base. In compounds 23.3, Y is a leaving group such as, but not limited to, bromide, chloride, iodide, *p*-toluenesulfonate, trifluoromethanesulfonate, or methanesulfonate.

For instance, 23.6 dissolved in DMF, is treated with one equivalent of sodium hydride and one equivalent of (toluene-4-sulfonylmethyl)-phosphonic acid diethyl ester 23.4, prepared according to the procedures in *J.Org. Chem.* 1996, 61, 7697, to give fluoro-cytosine phosphonate derivative 5, in which the linkage is a methylene group. Using the above procedure, but employing different phosphonate reagents 23.3 in place of 23.4, the corresponding products 23.2 bearing different linking groups are obtained.

Example 24. Synthesis of Representative Compounds of Formula 25

20 Representative compounds of the invention can be prepared as illustrated above. Phosphonate substituted analogs are prepared by reaction of furanoside purine nucleosides, structure 24.1 (obtained as described in US Patent 5,185,437

col. 9 ln. 16 to col. 35 ln. 19 and references cited therein) with the respective alkylating reagents 24.4. Illustrated above is the preparation of the phosphonate linkage to furanoside nucleoside cores through the 5'-hydroxyl group. Parent analog 24.1 is dissolved in a solvent such as, but not limited to, DMF or THF, and is treated with a phosphonate reagent bearing a leaving group in the presence of a suitable organic or inorganic base. In compounds 24.4, X is a leaving group such as, but not limited to, bromide, chloride, iodide, *p*-toluenesulfonate, trifluoromethanesulfonate, or methanesulfonate.

For instance, 24.5 (obtained as described in US Patent 5,185,437 col. 9 ln. 16 to col. 35 ln. 19 and references cited therein) is dissolved in DMF, is treated with three equivalents of sodium hydride and two equivalents of (toluene-4-sulfonylmethyl)-phosphonic acid diethyl ester 24.6, prepared according to the procedures in *J. Org. Chem.* 1996, 61, 7697, to give the corresponding phosphonate 24.7, in which the linkage is a methylene group. Using the above procedure, but employing different phosphonate reagents 24.4 in place of 24.6, the corresponding products 24.2 bearing different linking groups are obtained.

20

Example 25. Synthesis of Representative Compounds of Formula 26

Representative compounds of the invention can be prepared as illustrated above. Phosphonate substituted analogs 25.3 are prepared by reacting glycal 25.8 (obtained as described in *J. Am. Chem. Soc.* 1972, 94, 3213; in some cases
5 the nucleoside bases may need prior protection) with the respective phosphonate alcohols 25.9, followed by treatment with iodine monobromide (*J. Org. Chem.* 1991, 56, 2642-2647). Elimination of the resulting iodide followed by reduction with palladium on carbon provides the desired product 25.3.

For instance, dihydrofuran 25.10 is dissolved in CH₂Cl₂ and is combined with 3.5 equivalents of diethyl(hydroxymethyl) phosphonate. The resulting solution is treated with two equivalents of iodine monobromide at -25 °C. The
15 resulting phosphonate-iodide is treated with DBU and reduced under hydrogenation conditions to afford the desired product 25.12. Using the above procedure, but employing different phosphonate reagents 25.9 in place of 25.11, the corresponding products 25.3 bearing different linking groups are obtained.

20

Example 26. Synthesis of Representative Compounds of Formula 27

$R_1 = H, \text{ alkyl, aryl, haloalkyl, alkenyl, aryl, aryl}$

$R_2 = H, \text{ alkyl, aryl, haloalkyl, alkenyl, aryl, aryl}$

- 5 Representative compounds of the invention can be prepared as illustrated above. Phosphonate substituted analogs 26.2 are prepared by reacting glycal 26.3 (obtained as described in *J. Am. Chem. Soc.* 1972, 94, 3213) with phenylselenenyl chloride followed by treatment with the respective phosphonate alcohols 26.4 in the presence of silver perchlorate (*J. Org. Chem.* 1991, 56, 2642-2647). Oxidation of the resulting chloride using hydrogen peroxide, followed by aminolysis treatment of uracil using triazole, 2-chlorophenyldichlorophosphate, pyridine and ammonia (*Bioorg. Med. Chem. Lett.* 1997, 7, 2567) and a palladium on carbon reduction provides the desired product 26.2.

15

For instance, 26.3 dissolved in CH₂Cl₂, is treated with one equivalent of phenyl selenyl chloride at -70 °C, followed by treatment with silver perchlorate in the presence of diethyl(hydroxymethyl) phosphonate to generate selenide 26.7. The phosphonate is transformed into the d4CP analog by first oxidation with hydrogen peroxide, followed by conversion of the uracil moiety to a cytosine, and finally hydrogenation to the desired product 26.8. Using the above procedure, but employing different phosphonate reagents 26.4 in place of 26.6, the corresponding products 26.2 bearing different linking groups are obtained.

In some cases conversions to desired compounds may require the use of suitable protecting groups for the amino group of cytosine. Similarly, using different natural and unnatural bases with appropriate protecting groups, other analogs containing a variety of bases can be prepared.

Org. Chem.* 1996, 61, 7697, to give ddC phosphonate **27.5** in which the linkage is a methylene group. Using the above procedure, but employing different phosphonate reagents **27.3** in place of **27.4**, the corresponding products **27.2** bearing different linking groups are obtained.

10 Example 31. Synthesis of Representative Compounds of Formula 32

Representative compounds of the invention can be prepared as illustrated above. Alcohol 31.3 can be prepared as described in *J. Chem. Soc., Perkin Trans. 1* 1994, 1477. Note that other base derivatives can be prepared in a similar manner starting with their respective bases. Displacement of the chloride

of 31.3 with an amine in ethanol under reflux conditions (US Patent 5,034,394, col. 9, ln. 60 to col. 10 ln. 21) provides the key intermediate alcohol. Treatment of this alcohol with the respective alkylating reagents 31.4, provides the desired phosphonate substituted analogs 31.2. In the above compounds, R₆ is H, R₇ is

Org. Chem.* 1996, 61, 7697) affords ABC phosphonate 31.7, in which the linkage is a
 methylene group. Using the above procedure, but employing different R₃, R₆, R₇
 15 and phosphonate reagents 31.4 in place of 31.6, the corresponding products 31.2 bearing different linking groups are obtained.

Example 32. Synthesis of Representative Compounds of Formula 33

Phosphonate substituted analogs 32.5 are prepared by reaction of 32.3 (for example, AZT (A 2169, Sigma Aldrich or obtained as described in US 4,724,232) or 3'-deoxythymidine (D 1138 Sigma Aldrich)) with the respective alkylating reagents 32.4. Further modification of either the base or the 3'-
- 10 substituent can be carried out as illustrated above. AZT is dissolved in a solvent such as, but not limited to, DMF and/or THF, and is treated with a phosphonate reagent bearing a leaving group, in the presence of a suitable organic or inorganic base. In compounds 32.4, X is a leaving group such as, but not limited to, bromide, chloride, iodide, *p*-toluenesulfonate, trifluoromethanesulfonate, or

Treatment of compound 32.5 with methyl hypobromite provides the 5-bromo-6-alkoxy analog 32.6 (*J. Med. Chem.* 1994, 37, 4297 and US Patent

00/22600). Compound 32.6 can be elaborated by reducing the 3'-azide to the amine and converting the amine to the corresponding acetyl to provide compounds 32.7.

For instance, 32.1 dissolved in DMF, is treated with one equivalent of sodium hydride and one equivalent of (toluene-4-sulfonylmethyl)-phosphonic acid diethyl ester 32.8 (prepared according to the procedures in *J. Org. Chem.* 1996, 61, 7697) to give AZT phosphonate 32.9, in which the linkage is a methylene group. Treatment with methyl hypobromite followed by hydrogenation provides analog 32.10. Using the above procedure, but employing different phosphonate reagents 32.4 in place of 32.8, the corresponding products 32.2 bearing different linking groups are obtained. Additionally, the R₃-R₅ groups can be varied to generate other compounds.

Introduction of the appropriately protected bases using Mitsunobu reaction conditions (*Tetrahedron Lett.* 1997, 38, 4037-4038; *Tetrahedron* 1996, 52, 13655) followed by acid mediated removal of the silyl protecting group (*J. Org. Chem.* 1980, 45, 4797)

10 and dithiane removal and *in situ* cyclization (*J. Am. Chem. Soc.* 1990, 112, 5583) produces furanoside 33.5. Introduction of phosphonate linkage using the appropriate alcohol in the presence of TMSOTf (*Synlett* 1998, 177) generates analog 33.2.

For instance, 3 equivalents of DIAD (in 3 portions) is added dropwise to a stirred solution of alcohol 33.4 and adenine (3 equivalents) in dioxane. The reaction is stirred for 20 hours. The resulting product is treated with

hydrochloric acid in ethanol for 15 hours and filtered. The residue is stirred with [bis(trifluoroacetoxy)iodo]benzene (1.5 equivalents) in methanol to generate 33.7. Lewis acid-mediated reaction (*Synlett* 1998, 177) of diisopropyl hydroxymethylphosphonate 33.8 (*Tetrahedron Lett.* 1986, 27, 1477) produces a diastereomeric mixture of phosphonates 33.9, in which the linkage is a methylene group. Using the above procedure, but employing different appropriately protected bases and phosphonate reagents 33.6 in place of 33.8, the corresponding products 33.2 bearing different linking groups are obtained.

10 Example 34. Synthesis of Representative Compounds of Formula 35

Representative compounds of the invention can be prepared as illustrated above. Phosphonate substituted analogs 34.2 are prepared by reaction of FTC (34.1) (obtained as described in US 5,914,331 col. 10 line 40 to col. 18 line 15 and references cited therein) with the respective alkylating reagents 34.3. Illustrated above is the preparation of phosphonate linkage to FTC through the 5'-hydroxyl group. FTC is dissolved in a solvent such as, but not limited to, DMF and/or THF, and is treated with a phosphonate reagent bearing a leaving group, in the presence of a suitable organic or inorganic base. In compounds 34.3, X is a leaving group such as, but not limited to, bromide, chloride, iodide, *p*-toluenesulfonate, trifluoromethanesulfonate, or methanesulfonate.

For instance, 34.1 dissolved in DMF, is treated with one equivalent of sodium hydride and one equivalent of (toluene-4-sulfonylmethyl)-phosphonic acid diethyl ester 34.4 (prepared according to the procedures in *J. Org. Chem.* 1996, 61, 7697) to give FTC phosphonate 34.5 in which the linkage is a methylene group. Using the above procedure but employing different phosphonate reagents 34.3 in place of 34.4, the corresponding products 34.2 bearing different linking groups can be obtained.

10 **Example 41. Synthesis of Representative Compounds of Formula 46**

- Representative compounds of the invention can be prepared as illustrated above. The 5'-hydroxyl group of ribavirin (41.2) can be selectively protected with an appropriate protecting group. The product, 41.3, can be treated with benzoyl chloride, an appropriate base, in the presence of catalytic amount of 4-dimethylaminopyridine, to convert 2'- and 3'-hydroxyl groups to their corresponding benzoyl esters, producing dibenzoate 41.4. The 5'-hydroxyl group can be selectively deprotected to afford alcohol 41.5. Following procedure
- 15
- 20

described for the analogous compound in US 6,087,482, Figure 2, dibenzoate 41.4 can be converted to 41.7 in a three-step sequence. Treating electrophile 41.7 with a coupling agent, such as trimethylsilyl trifluoromethanesulfonate, in the presence of an appropriate alcohol containing a phosphonate group can produce phosphonate 41.8. Treating 41.8 with aqueous sodium hydroxide can deprotect the 2'- and 3'-hydroxyl groups to provide diol 41.1. Note that R^{P1} and R^{P2} in 41.8 and 41.1 can be the same or different protecting groups.

Example 42. Synthesis of Representative Compounds of Formula 47

10

Representative compounds of the invention can be prepared as illustrated above. The synthesis of 3-cyano-1-(2,3,5-tri-O-acetyl-β-D-ribofuranosyl)-1,2,4-triazole (42.2) is described in US 2002/0156030 A1, page 6, paragraph 0078 to paragraph 0079. Using this starting material, one can synthesize compound 42.1 using the sequence of chemical transformations outlined above.

Appropriate protection and deprotection procedures (see Greene and Wuts, *Protective Groups in Organic Synthesis*, 1999) can be employed to prepare 42.3, in which the 5'-hydroxyl group is protected, while the 2'-, and 3'-

hydroxyl groups are not. Subsequent protection, deprotection procedures can introduce protecting groups such as benzoyl group to the 2'- and 3'-hydroxyls, leaving the 5'-hydroxyl group unprotected as in alcohol **42.4**. Oxidation can convert the primary alcohol in **42.4** to the corresponding carboxylic acid or its ester. An optional deprotection of the ester can give the acid **42.5** as product. Further oxidation using oxidant such as lead tetraacetate can convert acid **42.5** to electrophile **42.6**, in which the leaving group is an acetate. Treating **42.6** with an alcohol containing a phosphonate moiety in the presence of appropriate coupling agent, such as trimethylsilyl trifluoromethanesulfonate, affords phosphonate **42.8**. Finally, treating **42.8** with the procedure described in US 2002/0156030 A1, page 6, paragraph 0081, provides phosphonate **42.1**. Note that R^{P1} and R^{P2} in **42.7**, **42.8** and **42.1** do not need to be the same.

Example 43. Synthesis of Representative Compounds of Formula 48

Representative compounds of the invention can be prepared as illustrated above. Compound 43.2 can be prepared from 43.1 by a series of selective protections of the 2', 3', and 5'- hydroxyl groups to give 43.6. The 5'- hydroxyl can then be selectively deprotected to give alcohol 43.7. Compound 43.7 in an appropriate aprotic solvent can be treated with at least two equivalents of an appropriate organic or inorganic base, and an appropriate electrophile bearing a leaving group, as in the structure X-linker-POR^{P1}R^{P2}, where X is a leaving group, to produce phosphonate 43.8. Appropriate deprotection procedures can be employed to convert 43.8 to diol 43.2. Note that R^{P1} and R^{P2} in 43.8 and 43.2 do not need to be the same.

Suitable aprotic solvents include, but are not limited to dimethyl formamide, dimethyl sulfoxide, and *N*-methylpyrrolidinone. Suitable organic or inorganic base include, but are not limited to sodium hydride, potassium *t*-butoxide, and triethylamine. Suitable leaving groups include, but are not limited to, chlorine, bromine, iodine, *p*-toluenesulfonate, methanesulfonate, and trifluoromethanesulfonate.

Example 44. Synthesis of Representative Compounds of Formulae 49 and 50

Representative compounds of the invention can be prepared as illustrated above. Triol **44.1** can be converted to alcohol **44.9**, having an unprotected 2'-hydroxyl, by selecting appropriate protecting groups for the 3'- and 5'-hydroxyl groups through a series of protection and deprotection sequences. Alkylation of **44.9** by an electrophile containing a phosphonate as described in Example 43 can produce **44.10**. After appropriate deprotection, **44.10** can be converted to phosphonate **44.3**.

The preparation of **44.4** is illustrated above. The reaction sequence and conditions are similar to that of **44.2** and **44.3** described above.

Selective protection of the primary alcohol in 45.6 gives alcohol 45.7 (see Greene and Wuts, *Protective Groups in Organic Synthesis*, 1999). Compound 45.7 in an appropriate aprotic solvent is treated with at least one equivalents of an appropriate organic or inorganic base. Addition of an appropriate electrophile bearing a leaving group affords compound 45.8.

Final deprotection of the primary alcohol affords phosphonate 45.4. Note that R^{P1} and R^{P2} in the sequence from 45.8 to 45.4 do not need to be the same.

Examples 59 and 60

- 5 Synthetic methodologies and intermediate compounds that can be used to prepare analogs of formulae D, E, F and G are described in Examples 59 and 60. These compounds are representative examples of compounds of Formulae 62-65.

10

Example 59. Synthesis of Representative Compounds of Formulae 62 and 64

Representative compounds of the invention can be prepared as illustrated above. Betulinic Acid (59.1.1) may be purchased from Sigma (Cat. No. 85505-7) or alternatively isolated from the stem bark of *Ziziphus mauritiana* Lam. (Rhamnaceae) as described in WO 02/16395 A1. Dihydrobetulinic acid is obtained by hydrogenation of betulinic acid as described in WO 02/16395 A1. Example 59 illustrates the synthesis of betulinic and dihydrobetulinic derivatives D and F.

10 The hydroxyl group of betulinic acid 59.1.1 is first protected with a suitable protecting group, such as benzyl ether as described in Greene and Wuts, *Protecting Groups in Organic Synthesis*, third edition, John Wiley and Sons, Inc. The protected hydroxyl is then converted into the acid chloride 59.2 which is then treated with an amine phosphonic acid of the general formula 59.3 to form

the amide 59.4. Deprotection of the hydroxyl gives products of the general formula 59.1. Dihydrobetulinic acid can be treated in exactly the same manner as 59.1 to give products of the general formula F.

5

For instance, betulinic acid is dissolved in a suitable solvent such as, DMF and treated with 2 equivalents of benzyl bromide along with an appropriate base such as NaH. The undesired benzyl protected carboxylate is removed by treatment with aqueous K₂CO₃ to give the benzyl ether which is then treated with 4 equivalents of oxalyl chloride in a suitable solvent, such as chloroform or methylene chloride (as described in *J. Med. Chem* 2002, 45, 4271-4275) to give 59.5. Acid chloride 59.5 is then treated with 2 equivalents of diethyl 2-

aminoethyl-1-phosphonate 59.6 (prepared as described in *J. Med. Chem.* 1998, 41, 4439-4452), along with 4 equivalents of a tertiary amine such as, for example, triethylamine to give the amide 59.7. Final deprotection of the benzyl ether is achieved by treatment with lithium di-*tert*-butylbiphenyl in THF at -78° (as described in *J. Am. Chem. Soc.* 1991, 113, 8791-8796) followed by purification using reverse-phase or normal phase chromatography to give 59.8. Using the above procedure, but employing different phosphonate reagents 59.3 in the place of 59.6, the corresponding products of general type D and F bearing different linking groups can be prepared.

Representative compounds of the invention can be prepared as illustrated above. Example 60 describes the synthesis of phosphonate derivatives of betulinic and dihydrobetulinic acid of the general formula E and G. Betulinic Acid 60.1 is treated with, for example, an appropriately substituted acid chloride (as described in *Tetrahedron Lett.* 1997, 38, 4277-4280) to form halide

derivative 60.9. Halide 60.9 is then treated with a hydroxyl phosphonic acid of the general formula 60.10 along with a suitable base to give compound 60.11. Dihydrobetulinic acid can be treated in exactly the same manner as 60.1 to give products of the general formula G.

5

For instance, 60.1 is dissolved in a suitable solvent such as THF, treated with 2 equivalents of a suitable base, such as triethylamine, and 2 equivalents of bromoacetyl chloride to give compound 60.12. The bromo derivative 60.12 is then treated with diethyl hydroxymethylphosphonate (which can be purchased from Sigma (Cat. No. 39262-6)) along with a suitable base, such as Cs_2CO_3 (as described in *Tetrahedron Lett.* 1999, 40, 1843-1846) to give compound 60.14. Dihydrobetulinic acid can be treated in exactly the same manner to give products of the general formula G. Using the above procedure, but employing different phosphonate reagents 60.10 in the place of 60.13, the corresponding products E and G bearing different linking groups can be prepared.

Examples 61-63

The analogs described in Examples 61-63 show a methylene group as the linker. The linker may, however, be any other group described in this specification.

Example 61. General Route to Representative Compounds of Formula 66*Cyclobutanes:*10 **4-membered ring nucleoside series:**

Representative compounds of the invention can be prepared as illustrated above. Compound 61.1 (Base = G), described in the literature, was shown to have reasonable anti-HIV activity (50-100 μ M, cf. lubocavir 30 μ M). Therefore, one target is its isosteric phosphonate derivative 61.2. Also, compound 61.1 can be derivatized to its phosphonate 61.4. In a similar manner, one may add a phosphonate group onto lubocavir to prepare carbocyclic 61.5, or alternatively carbocyclic isostere 61.6. Compounds 61.6 have a hydroxyl group analogous to the 3'-hydroxyl group of natural nucleosides. Such compounds may be incorporated into elongating strands by host DNA polymerases, a phenomenon

that may be associated with both carcinogenicity and mitochondrial toxicity.

Replacement of hydroxyl groups with fluorine atoms are established in medicinal chemistry. A well-known example is the replacement of the terminal hydroxyl group of the antibiotic chloramphenicol with a fluorine atom, providing
5 the superior drug florfenicol. In the case of 61.6 (or 61.8 and 61.9), the fluorine maintains many beneficial H-bonding interactions with RT that the pseudo-3'-hydroxyl of 61.5 provided, but will not provide a handle for incorporation into nucleic acids.

Considerations in the chemistry of derivatives 61.8 / 61.9: A protected
10 version of A maybe required (using, e.g., a pivalate) or a masked version of A (methoxy in lieu of aniline). If a masked version of A is required, synthesis of the base will be required. Yields for these processes in the synthesis of cyclobut-A and G derivatives are good-to-excellent. Fluorination reactions in the presence of unprotected A are well precedented to go in good yield (~90%)
15 when pyridine is used as a solvent. Acidic deprotection should not cause deglycosidation of base since there is no formal glycosidic linkage (O-C-N). Phosphonylation should proceed as for other derivatives in-house. All reactions proceed with useful kinetic diastereoselectivity. In base introduction reactions, equilibration conditions may be used to improve the kinetic diastereoselection
20 ratio. All compound made by this route are racemic. Enantiomerically pure compounds may be prepared by methods known to those of skill in the chemical arts.

Illustrated above is a synthetic sequence for the preparation of compound 61.16. Other nucleotide bases may optionally be used in this synthetic sequence.

5

Example 62. Representative Compounds of Formula 67

Cyclopropyl Nucleoside Series

10

Representative compounds of the invention can be prepared as illustrated above. The synthesis of cyclopropyl nucleosides of type 62.18 and 62.19 is well

documented by Chu and coworkers. Additional syntheses are reported by Csuk et al. Synthetic methods allow for the homochiral production of 62.18 and 62.19. Syntheses of compound types 62.17, 62.20, and 62.21 are also reported; these provide for racemic material.

5

Considerations in the synthesis of 62.17: Literature reports are for industrial processes. Racemic products: diastereomers are produced by a non-stereoselective cyclopropanation reactions and separation of the desired isomer with *cis* cyclopropyl substituents from that with *trans* may require rigorous separation techniques or alternate synthetic preparations because of the presence of an additional stereocenter at the THP anomeric position, as shown above in 62.23.

Considerations in the synthesis of 62.18 and 62.19: For the D series (compound 62.18), synthesis of key intermediate 62.29 (see below) can be preformed in 10 steps in 6 pots (24% overall yield from an abundant starting material, 1,2:5,6-di-*O*-isopropylidene-D-mannitol. Purine bases can be constructed from free amine 62.29. Phosphonate synthesis proceeds well according to known methodology. For the L series, the starting material is vitamin C.

Example 63. Synthesis of Representative Compounds of Formula 68

Vinylic Nucleoside Series

5

Representative compounds of the invention can be prepared as illustrated above. There are only a few reports of compound types 63.33 and 63.34 in the literature. Most reports provide for the syntheses of *trans* isomers 63.34. The one report that discusses *cis* isomers 63.33 does not state clear separation conditions from the mixture of *cis* and *trans* compounds formed. The *cis* isomers best resembles the geometry of the nucleoside antiviral agents and are therefore important compounds. Modeling studies indicate that 63.33 will be accommodated by the RT active site. However, when minimized in the RT active site side-by-side with tenofovir, some of the base stacking interactions

that provide binding energy between the inhibitor and the template strand may be lost.

5 Example 64. Synthesis of Representative Compounds of Formula 69

Representative compounds of the invention can be prepared as illustrated above. In WO 01/10429 A2, the synthesis of 64.1 was fully described using D-gulonolactone as the starting material. The secondary alcohol in 64.1 can be optionally protected with an appropriate protecting group (e.g. a silyl protecting group) to give 64.2 (See Greene and Wuts, *Protective Groups in Organic Synthesis*, 1999). Compound 64.3 can be optionally deprotected to give 64.4 containing the secondary alcohol. Compound 64.4 in an appropriate aprotic solvent can be treated with at least one equivalent of an appropriate organic or inorganic base. An appropriate electrophile bearing a leaving group is added to produce compound 64.5. Suitable aprotic solvents include, but are not limited to,

dimethyl formamide, dimethyl sulfoxide, and *N*-methylpyrrolidinone. Suitable organic or inorganic base include, but are not limited to, sodium hydride, potassium carbonate, and triethylamine. Suitable leaving groups include, but are not limited to, chlorine, bromine, iodine, *p*-toluenesulfonate, methanesulfonate, and trifluoromethanesulfonate.

The isopropylidene group in 64.5 can be removed to provide phosphonate 64.6. Various procedures for the removal of the isopropylidene group are described in Greene and Wuts, *Protective Groups in Organic Synthesis*, 1999. Note that R^{P1} and R^{P2} in 64.5 and 64.6 do not need to be the same.

A specific preparation of phosphonate 64.6 is illustrated above. The secondary alcohol in 64.7 can be protected with *t*-butyldimethylsilyl (TBDMS) group to give 64.8 (See Greene and Wuts, *Protective Groups in Organic Synthesis*, 1999). Compound 64.8 can be alkylated by treating a mixture of 64.8 and 64.9 with sodium cyanoborohydride. The aldehyde 64.9 can be prepared using the procedure outlined in below.

The tertiary amine 64.10 can be treated with tetrabutylammonium fluoride in THF to remove the TBDMS protecting group. Compound 64.11 can be treated with at least one equivalent of potassium *tert*-butoxide in dimethylformamide. The phosphonate-containing electrophile shown above is added to produce 64.12. The isopropylidene group in 64.12 can be removed by treating 64.12 with an aqueous solution of hydrochloric acid to give 64.13. The *para*-toluenesulfonate of diethyl hydroxymethylphosphonate can be prepared in a single step from diethyl hydroxymethylphosphonate and *para*-toluenesulfonyl chloride in pyridine and diethyl ether (see Holy, et al., *Collect. Czech. Chem. Commun.* 1982, 47, 3447-3463).

Example 65. Synthesis of Representative Compounds of Formulae 70 and 71

15

Representative compounds of the invention can be prepared as illustrated above. The synthesis of 65.1 can be performed as outlined in WO 01/10429 A2, using D-gulonolactone as the starting material. Treating 65.1 with hydrochloric acid can remove the isopropylidene group. The two secondary alcohols in diol 65.2 can be non-selectively protected with an appropriate protecting group to generate a mixture of 65.3 and 65.4. These two products can be converted to

65.6 and 65.8, respectively, using procedures described in Example 64 (from 64.1 to 64.6).

5

The preparation of specific examples of Compounds of Formulae 70 and 71 are illustrated above. The details about introducing and removing protecting groups can be found in Greene and Wuts, *Protective Groups in Organic Synthesis*, John Wiley and Sons, Inc., 1999. Other procedures are similar to those described in Example 64.

10

Example 66. Synthesis of Representative Compounds of Formula 72

Representative compounds of the invention can be prepared as illustrated above. In the above scheme, R^4 and R^5 are appropriate protective groups.

- 5 Group X is either hydroxyl (or oxygen) or thiol (or sulfur), or appropriately protected hydroxyl or thiol. Additionally, R^5 can be a cyclic protecting group for both the hydroxyl and X. The general method for the preparation of intermediates 66.3, 66.4, 66.5, and final product 66.6, are described in WO 03/020222 A2 page 28 line10 to page 53 line 22, as well as the references cited
- 10 therein. Additional description is provided in WO 01/32153 A2 page 41 line 3 to page 56 line 29 and references cited therein. Other good sources of information for transformation from 66.5 to 66.6 are Townsend, *Chemistry of Nucleosides and Nucleotides*, Plenum Press, 1994; and Vorbruggen and Ruh-Pohlenz, *Handbook of Nucleoside Synthesis*, John Wiley & Sons, Inc., 2001.

A specific example for the synthesis of a dioxolane nucleoside analog is illustrated above. Treating the mixture of 66.2.1 and 66.2.2 with *p*-toluenesulfonic acid, followed by removal of the benzyl protecting group on the carboxylic acid produces a mixture of carboxylic acids 66.2.3 and 66.2.4.

5 Treating acid 66.2.3 with lead(IV) tetraacetate gives acetate 66.2.5, which can be converted to nucleoside 66.2.6 under the reaction conditional described above.

Treating acid 66.2.4 with same reaction procedures for 66.2.3 to 66.2.6 can

10 generate a different diastereomer 66.2.8, which is an L-nucleoside analog.

A specific example for the synthesis of a oxathiolane nucleoside analog is illustrated above. The syntheses of 66.3.6 and 66.3.8 are analogous to that of 66.2.6 and 66.2.8 described above.

Preparation And Availability Of Starting Materials:

- 10 Compound 66.2.1 can be prepared from commercially available starting material 66.4.1 (available from Acros, catalog number 34693-0050 or 34693-0250, or from Epsilon, catalog number 95040) following the method illustrated above. Compound 66.2.2 can be prepared from commercially available starting material 66.4.2 (Fluka, catalog number 59437) following the method illustrated
- 15 above. The preparation of 66.3.2 was described in WO 03/020222 A2 page 34 line 7 to page 36 line 5, and references cited therein.

R₂ = H, alkyl, aryl, haloalkyl, alkenyl, aryl, aryl

20

Representative compounds of the invention can be prepared as illustrated above. The desired phosphonate substituted analogs are prepared by first reacting glycal **67.3** (obtained as described in *J. Am. Chem. Soc.* 1972, 94, 3213) with phenylselenenyl chloride followed by treatment with the respective phosphonate alcohols **67.4** in the presence of silver perchlorate (*J. Org. Chem.* 1991, 56, 2642-2647). Oxidation of the resulting chloride using hydrogen peroxide provides the desired phosphonate **67.2**.

For instance, **67.3** dissolved in CH_2Cl_2 , is treated with one equivalent of phenyl selenenyl chloride at -70°C followed by silver perchlorate in the presence of diethyl(hydroxymethyl) phosphonate (**67.5**). The phosphonate is transformed into the d4T analog **67.6** by oxidation with hydrogen peroxide. Using the above procedure, but employing different phosphonate reagents **67.4** in place of **67.5**, the corresponding products **67.2** bearing different linking groups are obtained. Additionally, analogs containing a variety of bases can be prepared by starting with the appropriately protected glycals (see examples in: *J. Am. Chem. Soc.* 1972, 94, 3213).

Example 68. Synthesis of Representative Compounds of Formula 74

Representative compounds of the invention can be prepared as illustrated above. The desired phosphonate substituted analogs are prepared by reaction of d4T (68.1) (obtained as described in US 4,978,655 col. 2 ln. 46 to col. 3 ln. 47) with the respective alkylating reagents 68.3. Illustrated above is the preparation of phosphonate linkage to d4T through the 5'-hydroxyl group. D4T is dissolved in a solvent such as, but not limited to, DMF or THF, and is treated with a phosphonate reagent bearing a leaving group in the presence of a suitable organic or inorganic base. In compounds 68.3, X is a leaving group such as, but not limited to, bromide, chloride, iodide, *p*-toluenesulfonate, trifluoromethanesulfonate, or methanesulfonate.

For instance, 68.1 dissolved in DMF, is treated with one equivalent of sodium hydride and one equivalent of (toluene-4-sulfonylmethyl)-phosphonic acid diethyl ester 68.4 (prepared according to the procedures in *J. Org. Chem.* 1996, 61, 7697) to give d4T phosphonate 68.5, in which the linkage is a methylene group. Using the above procedure, but employing different phosphonate reagents 68.3 in place of 68.4, the corresponding products 68.2 bearing different linking groups are obtained. In a similar manner, using a variety of d4Ts possessing different natural and non-natural nucleoside bases with the appropriate protecting groups, numerous other valuable analogs can be obtained.

- 5 Representative compounds of the invention can be prepared as illustrated above. The phosphorous-containing compounds of the present invention of Formula 75 can be readily prepared according to the conventional synthetic procedures exemplified in Schemes 69.1-69.12 where a phosphonate-containing moiety may be attached using established chemical processes. The preparations
- 10 may be carried out from the precursor compounds described in both WO 02/30930 and WO 02/30931. The methods for these conversions from precursor compounds to the phosphorous-containing compounds are described in *Comprehensive Organic Transformations*, Richard C. Larock, ed, VCH, 1989; *Comprehensive Organic Synthesis*, Barry M. Trost and Ian Fleming eds.,
- 15 Pergamon Press, 1991. Protection of function groups during the transformation is described in *Protective Groups in Organic Synthesis*, Theodora W. Greene and Peter G. M. Wuts, eds., Wiley, 1999.

Example 70. Synthesis of Representative Compounds of Formula 76

- Representative compounds of the invention can be prepared as illustrated above. The core components of this reaction sequence are the transformations
- 5 from primary alcohol 70.3 to phosphonate 70.6. Appropriate oxidant(s) can convert the primary alcohol (5'-hydroxy) in 70.3 to a carboxylic acid or its corresponding ester. In the case of an ester, an additional deprotection step will give the carboxylic acid 70.4. A variety of oxidation procedures can be found in the literature and can be utilized here. These include, but are not limited to, the
- 10 following methods: (i) pyridinium dichromate in Ac₂O, *t*-BuOH, and dichloromethane producing the *t*-butyl ester, followed by deprotection using a reagent such as trifluoroacetic acid to convert the ester to the corresponding carboxylic acid (see Classon, et al., *Acta Chem. Scand. Ser. B* 1985, 39, 501-504; Cristalli, et al., *J. Med. Chem.* 1988, 31, 1179-1183); (ii) iodobenzene diacetate and 2,2,6,6-tetramethyl-1-piperidinyloxy, free radical (TEMPO) in acetonitrile,
- 15 producing the carboxylic acid (see Epp, et al., *J. Org. Chem.* 1999, 64, 293-295; Jung et al., *J. Org. Chem.* 2001, 66, 2624-2635); (iii) sodium periodate, ruthenium(III) chloride in chloroform producing the carboxylic acid (see Kim, et al., *J. Med. Chem.* 1994, 37, 4020-4030; Homma, et al., *J. Med. Chem.* 1992, 35, 2881-2890); (iv) chromium trioxide in acetic acid producing the carboxylic acid
- 20 (see Olsson et al.; *J. Med. Chem.* 1986, 29, 1683-1689; Gallo-Rodriguez et al.; *J. Med. Chem.* 1994, 37, 636-646); (v) potassium permanganate in aqueous

potassium hydroxide producing the carboxylic acid (see Ha, et al., *J. Med. Chem.* 1986, 29, 1683-1689; Franchetti, et al., *J. Med. Chem.* 1998, 41, 1708-1715); and (vi) nucleoside oxidase from *S. maltophilia* to give the carboxylic acid (see Mahmoudian, et al., *Tetrahedron* 1998, 54, 8171-8182).

- 5 The preparation of 70.5 from 70.4 using lead(IV) tetraacetate (LG = OAc) is described by Teng et al., *J. Org. Chem.* 1994, 59, 278-280 and Schultz, et al; *J. Org. Chem.* 1983, 48, 3408-3412. When lead(IV) tetraacetate is used together with lithium chloride (see Kochi, et al., *J. Am. Chem. Soc.* 1965, 87, 2052), the corresponding chloride is obtained (70.5, LG = Cl). Lead(IV)
- 10 tetraacetate in combination with *N*-chlorosuccinimide can produce the same product (70.5, LG = Cl) (see Wang, et al., *Tetrahedron: Asymmetry* 1990, 1, 527; and Wilson et al., *Tetrahedron: Asymmetry* 1990, 1, 525). Alternatively, the acetate leaving group (LG) can also be converted to other leaving group such as bromide by treatment of trimethylsilyl bromide to give 70.5 (see Spencer, et
- 15 al., *J. Org. Chem.* 1999, 64, 3987-3995).

- The coupling of 70.5 (LG = OAc) with a variety of nucleophiles was described by Teng et al., *Synlett* 1996; 346-348 and US 6,087,482; column 54 line 64 to column 55 line 20. Specifically, the coupling between 70.5 and diethyl hydroxymethylphosphonate in the presence of trimethylsilyl
- 20 trifluoromethanesulfonate (TMS-OTf) is described. Other compounds with the general structure of HO-linker-POR^{P1}R^{P2} can also be used so long as the functional groups in these compounds are compatible with the coupling reaction conditions. There are many examples in the published literature describing the coupling of 70.5 (LG = halogen) with a variety of alcohols. The reactions can be
- 25 facilitated with a number of reagents, such as silver(I) salts (see Kim et al.; *J. Org. Chem.* 1991, 56, 2642-2647; Toikka et al., *J. Chem. Soc. Perkins Trans. 1*, 1999, 13, 1877-1884), mercury(II) salts (see Veeneman et al.; *Recl. Trav. Chim. Pays-Bas.* 1987, 106, 129-131), boron trifluoride diethyl etherate (see Kunz et al., *Hel. Chim Acta* 1985, 68, 283-287), tin(II) chloride (see O'Leary et al., *J.*
- 30 *Org. Chem.* 1994, 59, 6629-6636), alkoxide (see Shortnacy-Fowler et al., *Nucleosides Nucleotides* 2001, 20, 1583-1598), and iodine (see Kartha et al., *J. Chem. Soc. Perkins Trans. 1*, 2001, 770-772). These methods can be selectively

used in conjunction with different methods in forming 70.5 with various leaving groups (LG) to produce 70.6.

The introduction and removal of protecting groups is commonly practiced in the art of organic synthesis. Many sources of information on transformations involving protecting groups are available in the published literature, e.g. Greene and Wuts, *Protecting Groups in Organic Synthesis*, 3rd Ed., John Wiley & Sons, Inc., 1999. The main purpose is to temporarily transform a functional group so that it will survive a set of subsequent reaction procedures. Afterward, the original functional group can be restored by a preconceived deprotection procedure. Therefore, the transformations from 70.1 to 70.2, from 70.2 to 70.3, and from 70.6 to 70.7 are intended to allow important transformations (e.g., from 70.3 to 70.6) to occur while preserving the functional groups that already exist in the core structures.

It should be understood that in the transformation 70.6 to 70.7, R^{P1} and R^{P2} need not remain unchanged. The final form of R^{P1} and R^{P2} can be selected from a variety of possible structures.

The scheme shown above provides a specific example for the general scheme discussed above. Compound 70.2.1 is prepared using method described

in the patent filing WO 01/90121 (page 115). The 5'-hydroxyl in 70.2.1 is protected as a *t*-butyldimethylsilyl (TBDMS) ether. The 2'- and 3'- hydroxyl groups can be protected as benzoyl (Bz) esters to give 70.2.2. The 5'-hydroxyl can then be deprotected to give 70.2.3. Oxidation using iodobenzene diacetate and 2,2,6,6-tetramethyl-1-piperidinyloxy, free radical (TEMPO) converts the primary alcohol to the corresponding acid 70.2.4. Further oxidation of 70.2.4 using lead tetraacetate can produce 70.2.5. Coupling between 70.2.5 and diethyl hydroxymethylphosphonate (available from Sigma-Aldrich, Cat. No. 39,262-6) effected by TMS-OTf can afford 70.2.6. Treating 70.2.6 with TMS-Br converts the phosphodiester to the corresponding phosphonic acid 70.2.7. Deprotection of the 2'- and 3'- hydroxyl gives 70.2.8 as an example of the generic structure 76, where Base is an adenine, R¹, R⁵, and R⁶ are hydrogen, R² is methyl group, R³ and R⁴ are hydroxyl groups, linker is a methylene group, and R^{P1} and R^{P2} are both hydroxyl groups.

The phosphonic acids in 70.2.7 and 70.2.8 are illustrative examples. Other forms of phosphonates can be accessed via the phosphonic acid, or other forms, such as the corresponding diesters.

Preparation And Availability Of Starting Materials for Examples 70-153

L-Nucleoside Analogs

Many compounds of Formula 76 with a sugar moiety in its L-configuration are either commercially available or can be prepared by

procedures described in the published literature. Many of the compounds illustrated in Examples 71 - 153 can be prepared from one of the precursors described in Example 70 (see section: Preparation And Availability Of Starting Materials). The enantiomers of other nucleoside analogs (the L-nucleosides) can be prepared from enantiomers of the precursors of 70.3.1, 70.3.2, and 70.3.3. This Example describes a preparation of the enantiomers of 70.3.1, 70.3.2, and 70.3.3.

10

The commercially available starting material 153.4.1 can be converted to 153.4.4, which is the enantiomer of 70.3.1, using the sequence of reactions outlined above. The osmium tetroxide catalyzed dihydroxylation introduces the diol selectively to the face opposite of the *tert*-butyldimethylsilyl (TBDMS) ether of the hydroxymethyl group.

The diol in intermediate 153.4.3 can be protected as its TBDMS ether. Diisobutylaluminum hydride reduction of the lactone at low temperature produces 153.4.5, which can be converted to 153.4.6 by acetylation.

Deprotection of 153.4.6 produces L-ribose (153.4.7). Acylation converts all hydroxyl groups in 153.4.7 to the corresponding benzoyl esters. Standard coupling reactions with a variety of nucleobases produces 153.4.10, which is the enantiomer of 70.3.3.

From 70.3.1, 70.3.2, and 70.3.3, L-nucleosides can be prepared using known procedures, many of which are discussed in previous sections, in the patents cited, and in the published literature.

Many compounds in Examples 70 - 153 have their corresponding L-analog starting materials described in the same patent. These L-nucleosides can then be used in the same reaction sequences to produce the phosphonate analogs of the L-nucleosides.

Example 154. Synthesis of Representative Compounds of Formulae 84 and 85

Representative compounds of the invention can be prepared as illustrated above. Direct alkylation of entecavir derivative 154.5 with a phosphonate attached to a leaving group can be performed in the presence of a suitable organic or inorganic base to obtain analogs of the types 154.2 and 154.3. Compound 154.5 is prepared from protected or deprotected intermediates described in US 5,206,244 and US 5,340,816. After reaction, a mixture of compounds 154.2 and 154.3 is furnished, which are separated by the appropriate chromatographic method.

For instance, entecavir (154.1) is treated with sodium hydroxide and reacted with diethyl phosphomethyltriflate to afford a mixture of 154.6 and 154.7 as illustrated above. Silica gel chromatography is employed to give pure samples of the separated products.

Example 155. Synthesis of Representative Compounds of Formulae 84 and 85

Representative compounds of the invention can be prepared as illustrated above. Compounds having the structure 155.4 are prepared from intermediate 155.8, which is derived from deprotected intermediates described in US

5,206,244 and US 5,340,816. Diol 155.8 is converted to glycol 155.9 through published procedures. Upon treatment with IBr in the presence of the appropriate phosphonate alcohol, glycol 155.9 is converted to iodide 155.10. Nysted methylenation provides alkene 155.12, whose hydroxy stereocenter is then inverted to give the final compound 155.4.

For instance, intermediate 155.13 is converted to glycol 155.14 (see *J. Am. Chem. Soc.* 1972, 94, 3213) and then treated with IBr and diethyl phosphomethanol to furnish iodide 155.15 (see *J. Org. Chem.* 1991, 56, 2642). Nucleophilic substitution of the iodide using AgOAc affords acetate 155.16. After methylenation using the procedure of Nysted (US 3,865,848; *Aldrichim. Acta* 1993, 26, 14), the acetate group is removed using sodium methoxide in methanol. The resulting alcohol is inverted by the Mitsunobo protocol, and a second acetate deprotection produces the desired compound 155.18.

Examples 195-199

- 5 Synthetic methodologies and intermediate compounds that can be used to prepare analogs of formulae H, I, J, and K are described in Examples 195-199. These compounds are representative examples of compounds of Formulae 77-80.

10

Three regions of mycophenolate mofetil can be utilized for the attachment of the phosphonate prodrug onto mycophenolic acid as demonstrated by compounds H, I, and K shown above. Also, the carboxylic acid can be replaced with a phosphonic acid that is part of the prodrug moiety as in compound J.

Representative compounds of the invention are illustrated above.

5 Example 196. General Route to Representative Compounds of Formula 81

196.1

196.3

Representative compounds of the invention can be prepared as illustrated above. The morpholino ethyl moiety can serve as a prodrug functionality to improve bioavailability and can be replaced with the phosphonate prodrug handle as shown above. Mycophenolic acid is commercially available, e.g., from Sigma Chemical Company, St. Louis, Mo. Activation of the carboxylic acid 196.1 in the presence of the free phenol, followed by addition of an alcohol carrying the phosphonate group, results in the formation of the desired product 196.3 (US 4,786,637).

- Specifically, mycophenolic acid 196.1 is dissolved in dichloromethane. Thionyl chloride is added followed by a catalytic amount of DMF. The reaction
- 5 mixture is stirred at room temperature for 3 hours, after which the volatile components are removed under vacuum. The phosphonate-alcohol is dissolved in dichloromethane and chilled to about 4 °C on an ice bath. The mycophenolic acid chloride 196.2 is dissolved in dichloromethane and added to the chilled solution. After stirring for 90 minutes at about 4 °C, the reaction mixture is
- 10 washed with water and then with aqueous sodium bicarbonate. The organic solution is dried and evaporated to yield the phosphonate prodrug 196.4.

Example 197. Synthesis of Representative Compounds of Formula 79

Representative compounds of the invention can be prepared as illustrated above. The C-4 phenol position provides a reactive handle for further analogs as

5 illustrated above. Once the carboxylic acid of 197.1 is blocked by morpholino ethyl, such as in compound 197.2, or a phosphonate prodrug as in compound 197.3, the phenol can be alkylated under basic conditions. Bases such as pyridine, potassium carbonate, or triethylamine are utilized. Leaving groups such as trifluoromethylsulfonate, mesylate, bromide, or iodide are attached to the

10 phosphonate prodrug subunit and reacted, in the presence of base, with compound 197.2. Compound 197.3 can either be used directly, or in the form of a salt, compound 197.4. Among the large number of salts that can be prepared, chloride and bisulfate salts are of particular utility.

Preparation of compound 197.4 is outlined in more detail above.

Compound 197.2 is prepared similar to compound 196.2 (described in an

- 5 Example above above). A solution of morpholino ethanol in dichloromethane is cooled to about 4 °C. The mycophenolic acid chloride 197.1.1 is dissolved in dichloromethane and added to the cooled solution. Stirring this solution for about 90 minutes gives compound 197.2. The reaction mixture is washed with water and dried with sodium sulfate. Removal of the solvent provides isolated
- 10 compound 197.2. Alkylation at the phenolic position of 197.2 is achieved by suspending the compound in pyridine. Triflate 197.2.1 is added to the solution and the mixture is stirred at room temperature for about 90 minutes. The reaction mixture is poured into water and the product is extracted with ethyl acetate. Removal of the organic layer provides compound 197.3. Hydrochloride
- 15 salt of 197.3 can optionally be prepared. Compound 197.3 is dissolved in isopropanol and the solution is added to a mixture of hydrogen chloride in

isopropanol. The hydrochloride salt 197.4 is collected by filtration and dried under vacuum.

Example 198. Synthesis of Representative Compounds of Formula 78

5

Representative compounds of the invention can be prepared as illustrated above. The carboxylic acid of mycophenolic acid can be replaced with a phosphonic acid that may also serve as a prodrug handle. In order to remove the carboxylic acid containing side chain, the acid chloride 197.2 (prepared in Example 197) is converted to ester 198.1. Protection of the phenol with a silyl group, followed by dihydroxylation and cleavage of the diol generates aldehyde 198.3 (Pankiewicz, et al., *J. Med. Chem.* 2002, 45, 703), (Patterson et al., US 5,444,072). A Wittig reaction with ylide 198.3.1 carrying an appropriately protected phosphonate provides the desired compound 198.4. Final deprotection yields compound 198.5.

- Mycophenolate ester **198.1** can simply be prepared by stirring the acid chloride **198.1.1** with MeOH. Then, the phenol position of mycophenolate ester is protected by a silyl group such as TBS to provide compound **198.2**. Once the phenol position is protected, dihydroxylation using osmium tetroxide followed by periodate cleavage provides aldehyde **198.3**. Aldehyde **198.3** and excess of the ylide **198.3.1** are heated in benzene at reflux for about 24 hours. The reaction mixture is concentrated and the residue is purified by column chromatography to provide olefin **198.4** (Pankiewics et al., *J. Med. Chem.* 2002, 45, 703). A final deprotection using HF-pyridine yields the final product **198.5**.

Example 199. Synthesis of Representative Compounds of Formula 80

Representative compounds of the invention can be prepared as illustrated above. A phosphonate-attachment point can be unmasked after demethylation of

5 mycophenolate ester 199.1.1. For this purpose, the 4-OH needs to be masked with a protecting group such as a silyl group. Once the 6-OMe is demethylated and alkylated, the protecting group at position 4 is removed to reveal the final product 199.4. The morphonyl ethanol group is installed early and carried through the alkylation steps. A different protecting group may be installed

10 initially and removed later. In such a synthesis, the last step is the formation of the morpholinoethyl ester compound.

Synthesis of compound 199.4 is shown above. Phenol 199.1.1 is protected with TBS group in CH_2Cl_2 using imidazole as base to yield 199.5.

- 5 Demethylation is performed using thiolate nucleophiles to generate compound 199.6. A variety of other methods are also available in literature as described in *Protective Groups in Organic Synthesis* by Greene and Wuts. Alkylation of the 6-OH using a triflate of the phosphonate prodrug proceeds well using K_2CO_3 or TEA to provide 199.7. Final deprotection to remove the TBS group provides
- 10 product 199.4.

Synthesis of olefins and linkers to phosphonates

Representative compounds of the invention can be prepared as illustrated in the following schemes.

The phenacetaldehyde (5.3 g, 15.8 mmol) in toluene (50 mL) was heated at 100°C with 2-(triphenyl-phosphanylidene)-propionaldehyde (6.8 g, 20.5 mmol) overnight. After concentration, the residue was purified by silica gel chromatography to provide 4.24 g (72%) of the unsaturated aldehyde as a pale yellow solid. ^1H NMR (300 MHz, CDCl_3) δ 0.00 (s, 9H), 1.10- 1.21 (m, 2H),

1.87 (s, 3H), 2.16 (s, 3H), 3.67- 3.76 (m, 2H), 3.74 (s, 3H), 4.27- 4.39 (m, 2H),
5.11 (s, 2H), 6.40- 6.48 (m, 1H), 9.2 (s, 1H).

5

The trimethylsilyl-protected aldehyde is treated with diethylphosphite in a solvent such as acetonitrile in the presence of a base such as triethylamine to afford the hydroxy phosphonate, according to a procedure such as that reported in *Tetrahedron*, 1995, 51, 2099. The hydroxy phosphonate is *O*-alkylated and then the protecting group is removed by treatment with either trifluoroacetic acid or tetrabutylammonium fluoride to generate the desired methoxy phosphonate analog.

Alternatively, the aldehyde is mixed with diethyl (2-aminoethyl)phosphonate and treated with a reducing agent such as sodium triacetoxyborohydride to generate the amino phosphonate analog.

15

A solution of 4-[6-methoxy-7-methyl-3-oxo-4-(2-trimethylsilyl-ethoxy)-1,3-dihydro-isobenzofuran-5-yl]-2-methyl-but-2-enal (103 mg, 0.27 mmol) in methanol (5 mL) was cooled to 0 °C. A solution of CeCl₃ (0.68 mL, MeOH: H₂O, 9:1) was added, followed by LiBH₄ (0.14 mL, 0.28 mmol of a 2M solution in THF). The ice bath was removed and the reaction mixture was allowed to warm to room temperature. The reaction mixture was stirred for an additional 40 minutes whereupon TLC indicated complete consumption of starting aldehyde. The reaction was worked up by addition of aqueous 1N HCl (0.5 mL) and the product was extracted with CH₂Cl₂. The organic layer was washed with saturated aqueous sodium bicarbonate solution and brine. The organic layer was concentrated under reduced pressure and the residue was purified by silica gel chromatography to provide 100 mg (97%) of the product as a clear liquid. ¹H NMR (300 MHz, CDCl₃) δ 0.00 (s, 9H), 1.20 (dd, 2H, *J* = 7, 8 Hz), 1.81 (s, 3H), 2.13 (s, 3H), 3.38- 3.50 (m, 2H), 3.74 (s, 3H), 3.95 (s, 2H), 4.27 (dd, 2H, *J* = 7, 8 Hz), 5.08 (s, 2H), 5.17- 5.44 (m, 1H).

Polymer-supported triphenylphosphine is soaked in DCM for 1 hour. The allylic alcohol and carbon tetrabromide are sequentially added. When the reaction is complete, the mixture is filtered and the filtrate concentrated. The bromide is purified as necessary by chromatography.

- The allylic bromide is treated in an inert organic solvent such as dimethylformamide with an alkali metal salt of ethyl diethoxyphosphorylacetate (prepared by reacting ethyl diethoxyphosphorylacetate with sodium hexamethyldisilazide or sodium hydride) to afford the ethoxycarbonyl phosphonate, according to a procedure such as that described in WO 95/22538. The carboxylic ester group is converted to both the carboxylic amide and the hydroxymethyl groups according to the methods conventionally utilized for amide formations and ester reductions. For example, the carboxylic ester is saponified with aqueous lithium hydroxide. The acid is activated with ethyl chloroformate and reduced with sodium borohydride to generate, after removal of the protecting group, the hydroxymethyl phosphonate analog. The acid is also converted to its acyl chloride and then reacted with ethylamine to afford the amide analog.

The aryl acetaldehyde is coupled with 2-(diethoxyphosphoryl)-but-3-enoic acid ethyl ester to generate the 2-vinyl substituted ester, according to a procedure such as that reported in *Synthesis*, 1999, 282. The 2-vinyl group is converted to the 2-cyclopropyl group under cyclopropanation conditions such as those described in *Tetrahedron Lett.* 1998, 39, 8621. The ester is converted to the alcohol, which, optionally, can be further subjected to reactions such as that described below to generate various phosphonate-containing mycophenolic acid analogues.

The allylic alcohol is treated with bromomethylphosphonic acid diisopropyl ester in the presence of a base such as lithium *t*-butoxide in a solvent such as dimethylformamide. The phenol protecting group is then removed by treatment with trifluoroacetic acid.

15

The phenacetaldehyde can alternatively be converted to the allyl phosphonium salt, according to a procedure such as that reported in *J. Org. Chem.* 1987, 52, 849. The phosphonium salt is then treated with the commercially available 3,3,3-trifluoro-2-oxo-propionic acid ethyl ester and a

20

base such as sodium hydride to generate the 2-trifluoromethyl substituted ester. The ester is converted to the alcohol, which, optionally, can be further subjected to reactions described earlier to generate mycophenolic acid analogues with various side chains containing the phosphonate group.

Example 205. Preparation of Representative Compounds of Formula

20 Introduction of linkers to phosphonates:

Representative compounds of the invention can be prepared as illustrated above. The phenols shown in herein may optionally be alkylated with the

reagent of choice. Optionally, the phosphonate moiety will be part of such a reagent; alternatively it will be introduced in a subsequent step by a variety of means, of which three are illustrated above. For example, an alkyl halide may be heated with triethylphosphite in a solvent such as toluene (or other Arbuzov reaction conditions: see Engel, R., *Synthesis of Carbon-Phosphorus Bonds*, CRC Press, 1988). Alternatively, an epoxide may be reacted with the anion of a dialkyl phosphinate. In a further example, the phosphonate reagent may be the electrophile; for example, an acetylide anion may be condensed with phosphorus oxychloride and the intermediate dichlorophosphonate quenched with ethanol to generate the diethyl ester of the desired phosphonic acid.

20 **Synthesis of 210.2:** To a solution of **210.1** (1.31 g, 2.3 mmol) in 5 mL of anhydrous *N,N*-dimethylformamide was added benzyl chloromethyl ether (0.54 g, 3.45 mmol), *N,N*-diisopropylethylamine (446 mg, 0.60 mL, 3.45 mmol). The mixture was stirred at 23 °C for 4 hours. Water was added. The mixture was extracted with ethyl acetate. The organic layer was washed sequentially with 1
25 M aqueous citric acid, saturated sodium bicarbonate, and brine. It was dried over anhydrous sodium sulfate and concentrated in vacuo to give a crude product as a yellow oil, which was used in the next step without further purification.

The crude product obtained above was dissolved in 9 mL of THF. The solution was cooled to 0 °C. A 1 M solution of TBAF (4.6 mL, 4.6 mmol) was

added via syringe. The mixture was warmed to 23 °C and stirred for another 2 hours. An additional 2.3 mL of 1 M TBAF was added. The mixture was stirred for another 2 hours at 23 °C. Saturated aqueous ammonium chloride was added to the solution. The mixture was evaporated in vacuo to remove most of THF.

Example 211: Preparation of Representative Compounds of Formula 89

25

Representative compounds of the invention can be prepared as illustrated above. Analogs attached to the 4-position of levamisole of the type 211.2 are prepared from the R³-protected starting material 211.3. Following resolution of the enantiomers, the protecting group is cleaved and the appropriate phosphonate is alkylated on to the phenol 211.5.

As an example, the racemic methyl ether 211.6 is synthesized by a published procedure (*J. Med. Chem.* 1966, 9, 545-551). The desired enantiomer 211.7 is resolved between a chiral solid and an achiral supercritical fluid phase (*Tetrahedron: Asymmetry* 1999, 10, 1275-1281). After reaction with BBr₃, phenol 211.5 is furnished. Final alkylation with diethyl phosphomethyltriflate affords the desired phosphonate 211.8.

Example 212: Preparation of Representative Compounds of Formulae 90 and 93

Representative compounds of the invention can be prepared as illustrated above. Triol 212.2 can be selectively alkylated with an appropriate phosphonate-containing alkylating agent. Deprotection of nitrogen affords phosphonate 212.1.

A specific compound of Formula 90 or 93 can be prepared as illustrated above. The Boc-protected (1S)-1-(9-deazaguanin-9-yl)-1,4-dideoxy-1,4-imino-D-ribitol, compound 212.3, is prepared by stirring the (1S)-1-(9-deazaguanin-9-yl)-1,4-dideoxy-1,4-imino-D-ribitol (WO 99/19338 and Evans, G. B. et al., *Tetrahedron*, 2000, 56, 3053, also reported in Evans, G. B. et al., *J. Med. Chem.* 2003, 46, 3412) with BOC anhydride as described in Greene, T., *Protective Groups In Organic Synthesis*, Wiley-Interscience, 1999. Compound 212.3 is then treated in a solvent such as tetrahydrofuran or dimethylformamide with a base such as sodium hydride. When bubbling ceases, diethyl phosphonomethyltriflate (prepared according to *Tetrahedron Lett.*, 1986, 27, 1477) is added, yielding the desired phosphonate 212.4 after deprotection of the BOC group using trifluoroacetic acid (TFA).

The Boc-protected (1S)-1-(9-deazaguanin-9-yl)-1,4-dideoxy-1,4-imino-D-ribose, compound 213.4, is prepared by stirring the (1S)-1-(9-deazaguanin-9-yl)-1,4-dideoxy-1,4-imino-D-ribose (WO 99/19338 and Evans, G. B. et al., *Tetrahedron*, 2000, 56, 3053, also reported in Evans, G. B. et al., *J. Med. Chem.* 2003, 46, 3412) with BOC anhydride as described in Greene, T., *Protective groups in organic synthesis*, Wiley-Interscience, 1999. Subsequent protection of the primary alcohol using a TBS group can be achieved using TBSCl and imidazole in solvents such as CH₂Cl₂ as described in Greene, *Protective Groups In Organic Synthesis*, Wiley-Interscience, 1999, to provide compound 213.4. Compound 213.4 is then treated in a solvent such as tetrahydrofuran or dimethylformamide with a base such as sodium hydride. When bubbling ceases, diethyl phosphonomethyltriflate (prepared according to *Tetrahedron Lett.*, 1986, 27, 1477) is added, yielding a mixture of the desired phosphonate diester 213.5 and 213.6 after deprotection of the BOC group using trifluoroacetic acid (TFA). Compounds 213.5 and 213.6 can be also prepared via a more complicated 2'-OH protected analog of 213.4 followed by alkylation using the diethyl phosphonomethyltriflate to provide compound 213.5 exclusively. Compound 213.6 can also be prepared by installation of a different protecting group at the 3'-OH position, followed by deprotection of 2'-OH and

Example 214: Preparation of Representative Compounds of Formula 96

5

For example:

X = Cl, Br, I, OMs, OTs, OTf
where R₁ = Alkyl, Aryl

R₁ = H, alkyl, aryl, haloalkyl, alkenyl, aryl, aryl

R₂ = H, alkyl, aryl, haloalkyl, alkenyl, aryl, aryl

Bases = thymine, adenine, guanine, cytosine, uracil, inosine, diaminopurine.

Bases requiring protecting groups are to be suitably protected using protecting groups and conditions well known to those skilled in the art

Representative compounds of the invention can be prepared as illustrated above. The desired phosphonate substituted analogs are prepared by reaction of intermediate 214.5 (obtained as described in US Patent 5,464,826) with the respective alkylating reagents 214.6. Illustrated above is the preparation of phosphonate linkage to 2',2'-difluoronucleosides through the 5'-hydroxyl group. The appropriately protected base as described in US Patent 5,464,826 is dissolved in a solvent such as DMF, THF and is treated with a phosphonate reagent bearing a leaving group, for example, bromine, mesyl, tosyl, or trifluoromethanesulfonyl in the presence of a suitable organic or inorganic base.

For instance, 214.1 (obtained as described in US Patent 5,464,826) dissolved in DMF, is treated with two equivalents of sodium hydride and one equivalent of (toluene-4-sulfonylmethyl)-phosphonic acid diethyl ester 214.8, prepared according to the procedures in *J. Org. Chem.* 1996, 61, 7697, to give the corresponding phosphonate 214.9 in which the linkage is a methylene group. Using the above procedure but employing different phosphonate reagents 214.6 in place of 214.8 the corresponding products 214.2 bearing different linking groups are obtained.

Example 215: Preparation of Representative Compounds of Formula 97

Representative compounds of the invention can be prepared as illustrated above. Compounds **215.5** containing a variety of suitably protected bases as cited and prepared according to US Patent 5,464,826, can be converted to glycal **215.10** according to the process reported in *J. Am. Chem. Soc.* 1972, 94, 3213. Glycal **215.10** is then treated with IBr in the presence of alcohol **215.11** to provide intermediate **215.12** (see *J. Org. Chem.* 1991, 56, 2642). The iodide of intermediate **215.12** can be treated with AgOAc to provide the corresponding acetate, which is deacetylated in the presence of catalytic sodium methoxide in methanol. Treatment of the resulting alcohol with DEAD and PPh₃ in the presence of acetic acid, followed by another deprotection with catalytic sodium methoxide in methanol will provide intermediate **215.3**. The phosphonates of intermediates **215.3** can then be converted into their final desired forms.

For instance, glycal **215.14** is prepared according to the procedures cited above (U.S. Patent 5,464,826; *J. Am. Chem. Soc.* 1972, 94, 3213). Glycal **215.14** is then treated with IBr in the presence of diethyl phosphonomethanol, **215.8**, to provide intermediate **215.15** (see *J. Org. Chem.* 1991, 56, 2642). Intermediate **215.15** is then treated with AgOAc followed by deprotection with catalytic NaOMe in MeOH. This compound is then converted into **215.16** by a Mitsunobu reaction with DEAD/PPh₃ and HOAc in THF, followed by a second catalytic NaOMe/MeOH deprotection. Base conversion of uracil to cytosine is carried out prior to the acetyl deprotection using the procedures in *Bioorg. Med. Lett.* 1997, 7, 2567. At any point in the synthesis sequence where it is

appropriate, the phosphonate group may be converted into the phosphonate with the desired substitution. Using the above procedure but employing different phosphonate reagents 215.11 in place of 215.8 the corresponding products 215.3 bearing different linking groups are obtained.

Example 216: Preparation of Representative Compounds of Formula 98

Representative compounds of the invention can be prepared as illustrated above. The phosphorus containing merimepodib analog 216.2 is synthesized from parent compounds by alkylation. Merimepodib (216.1) is obtained by the procedure as described in US 6,054,472 and US 6,344,465. Shown above is the procedure for the synthesis of 216.2. Methoxy group of merimepodib (216.1) is demethylated to the phenolic OH using a suitable reagent, such as boron tribromide. The phosphonate moiety is introduced to the phenolic OH in a suitable aprotic solvent such as, DMF by treatment with the phosphonate reagent 216.7, bearing a leaving group, for example, bromine, mesyl, tosyl, or trifluoromethanesulfonyl, in the presence of a suitable organic or inorganic base.

20

For instance, a solution of 216.1 in dichloromethane is treated with boron tribromide to obtain the demethylated compound 216.8. Compound 216.8 is then treated with cesium carbonate and one equivalent of (trifluoromethanesulfonyloxy)methylphosphonic acid diethyl ester 216.9 to give merimepodib-phosphonate 216.10 in which the linkage is a methylene group as shown above. Using the above procedure but employing different phosphonate reagents 216.7, the corresponding products 216.2 bearing different linking group can be obtained.

Example 217: Preparation of Representative Compounds of Formulae 99 and 100

Representative compounds of the invention can be prepared as illustrated above. The imidazole containing intermediate 217.13 is synthesized from an aldehyde 217.12 by the procedure of Shih in *Tetrahedron Lett.* 1993, 34, 595.

Compound 217.12 is prepared by a two-step procedure described in US 5,807,876, US 6,054,472, and US 6,344,465. The imidazole is protected using suitable reagent, for example 2-(trimethylsilyl)ethoxymethyl (SEM) chloride, and the compound 217.14 is converted to 217.15 by the similar procedure described for the synthesis of 216.1 in US 6,054,472 and US 6,344,465. After the protecting group on the imidazole of 217.15 is removed, the phosphonate containing moiety is introduced to the imidazole as shown below.

For example, compound 217.15 is treated with tetrabutylammonium fluoride in THF under refluxing conditions and the resulting 217.16 is alkylated
 5 with 217.9 using sodium hydride as a base to obtain the two isomers 217.17 and 217.18, which are separated by chromatography.

Example 218: Preparation of Representative Compounds of Formula 101

Representative compounds of the invention can be prepared as illustrated above. Illustrated above is the preparation of merimepodib analog 218.5.

- 5 Tetrasubstituted benzene derivatives are obtained by literature procedures (Ichikawa and Ichibagase *Yakugaku Zasshi* 1963, 83, 103; Norio, A. *et al. Tetrahedron Lett.* 1992, 33(37), 5403). After the phenolic OH is protected with a suitable protecting group, for example benzyl group, the compound 218.21 is synthesized by the same procedure of the synthesis of 216.1 as described in US
- 10 6,054,472, and US 6,344,465. After the protecting group is removed, the phosphonate containing moiety is introduced to the phenolic OH using the phosphonate reagent 218.7, bearing a suitable leaving group.

For example, a solution of 218.22, which is obtained by the procedure of Norio et al. (*Tetrahedron Lett.* 1992, 33(37), 5403), is treated with sodium hydride and one equivalent of benzyl bromide in DMF to get 218.23.

Compound 218.23 is converted to 218.24 by a series of steps reported in US

6,054,472, and US 6,344,465 for the synthesis of 216.1 from 217.12. After the

benzyl protecting group of 218.24 is removed by catalytic hydrogenation, a phosphonate bearing moiety is attached by alkylation of the resulting phenol in DMF using sodium hydride and one equivalent of

(trifluoromethanesulfonyloxy)methylphosphonic acid diethyl ester 218.7 to give

218.25.

Example 219: Preparation of Representative Compounds of Formula 102

15

Representative compounds of the invention can be prepared as illustrated above. Synthesis of merimepodib analog 219.6 is shown above. Compound 219.26, an intermediate in the synthesis of 216.1, is treated with carbonyldiimidazole or triphosgene followed by the compound 219.27, which

20 has an handle to attach phosphonate moiety. Compound 219.27 bearing an extra substituent is synthesized from the tri substituted phenol with cyano and nitro groups, which is either commercially available or can be prepared by literature

procedures (Zolfigol, M. A. *et al. Indian J. Chem. Sect. B* 2001, 40, 1191; De Jongh, R. O. *et al. Recl. Trav. Chim. Pays-Bas* 1968, 87, 1327). The resulting 219.28 is converted to 219.29 using the procedure described in US 6,054,472, and US 6,344,465 for the synthesis of 216.1. The phosphonate moiety of 219.6 is attached after deprotection of the benzyl group of 219.29:

For example, the bromine substituent of compound 219.30 is substituted with cyano group by the procedure of De Jongh, R. O. *et al. (Recl. Trav. Chim. Pays-Bas* 1968, 87, 1327) and the methoxy group is converted to benzyloxy group as a protecting group, which affords compound 219.31. After selective reduction of cyano to aminomethyl group by borane, the amino group is protected with Boc group and then the reduction of the nitro group using tin (II) chloride generates compound 219.32. This substituted aniline 219.32 is then treated with a reaction mixture of the compound 219.26 and carbonyldiimidazole, as described for the synthesis of 216.1 in US 6,054,472, and US 6,344,465, to form the urea 219.33. Compound 219.33 is easily converted to 219.34, analog of 216.1 bearing benzyloxy group. Deprotection of the benzyl group using catalytic hydrogenation followed by attachment of a phosphonate moiety using 219.9 in the presence of cesium carbonate produces 219.34.

- Appropriate oxidant(s) can convert the primary alcohol (5'-hydroxy) shown in 518-1.3 to a carboxylic acid or its corresponding ester. In the case of an ester, an additional deprotection step will give the carboxylic acid, 518-1.4. A variety of oxidation procedures exist in the literature and can be utilized here.
- 10 These include but are not limited to the following methods: (i) pyridinium dichromate in Ac_2O , t-BuOH, and dichloromethane producing the t-butyl ester, followed by a deprotection using reagent such as trifluoroacetic acid to convert the ester to the corresponding carboxylic acid (see Classon, et al, *Acta Chem. Scand. Ser. B*; 39; 1985; 501-504. Cristalli, et al; *J. Med. Chem.*; 31; 1988;
- 15 1179-1183.); (ii) iodobenzene diacetate and 2,2,6,6-tetramethyl-1-piperidinyloxy, free radical (TEMPO) in acetonitrile, producing the carboxylic acid (See Epp, et al; *J. Org. Chem.* 64; 1999; 293-295. Jung et al; *J. Org. Chem.*; 66; 2001; 2624-2635.); (iii) sodium periodate, ruthenium(III) chloride in chloroform producing the carboxylic acid (see Kim, et al, *J Med. Chem.* 37;
- 20 1994; 4020-4030. Homma, et al; *J. Med. Chem.*; 35; 1992; 2881-2890); (iv) chromium trioxide in acetic acid producing the carboxylic acid (see Olsson et al; *J. Med. Chem.*; 29; 1986; 1683-1689. Gallo-Rodriguez et al; *J. Med. Chem.*; 37; 1994; 636-646); (v) potassium permanganate in aqueous potassium hydroxide producing the carboxylic acid (see Ha, et al; *J. Med. Chem.*; 29; 1986; 1683-
- 25 1689. Franchetti, et al; *J. Med. Chem.*; 41; 1998; 1708-1715.) (vi) nucleoside

oxidase from *S. maltophilia* to give the carboxylic acid (see Mahmoudian, et al; *Tetrahedron*; 54; 1998; 8171-8182.)

The preparation of 518-1.5 from 518-1.4 using lead(IV) tetraacetate (LG = OAc) was described by Teng et al; *J. Org. Chem.*; 59; 1994; 278-280 and
5 Schultz, et al; *J. Org. Chem.*; 48; 1983; 3408-3412. When lead(IV) tetraacetate is used together with lithium chloride (see Kochi, et al; *J. Am. Chem. Soc.*; 87; 1965; 2052), the corresponding chloride is obtained (1.5, LG = Cl). Lead(IV) tetraacetate in combination with N-chlorosuccinimide can produce the same product (1.5, LG = Cl) (see Wang, et al; *Tet. Asym.*; 1; 1990; 527 and Wilson et
10 al; *Tet. Asym.*; 1; 1990; 525). Alternatively, the acetate leaving group (LG) can also be converted to other leaving group such as bromide by treatment of trimethylsilyl bromide to give 518-1.5 ((see Spencer, et al; *J. Org. Chem.*; 64; 1999; 3987-3995).

The coupling of 518-1.5 (LG = OAc) with a variety of nucleophiles were
15 described by Teng et al; *Synlett*; 1996; 346-348 and US 6,087,482; Column 54 line 64 to Column 55 line 20. Specifically, the coupling between 518-1.5 and diethyl hydroxymethylphosphonate in the presence of trimethylsilyl trifluoromethanesulfonate (TMS-OTf) was described. It can be envisioned that other compounds with the general structure of HO-linker-POR^{P1}R^{P2} can also be
20 used so long as the functional groups in these compounds are compatible with the coupling reaction conditions. There are many examples in the published literature describing the coupling of 518-1.5 (LG = halogen) with a variety of alcohols. The reactions can be facilitated with a number of reagents, such as silver(I) salts (see Kim et al; *J. Org. Chem.*; 56; 1991; 2642-2647, Toikka et al;
25 *J. Chem. Soc. Perkins Trans. 1*; 13; 1999; 1877-1884), mercury(II) salts (see Veeneman et al; *Recl. Trav. Chim. Pays-Bas*; 106; 1987; 129-131), boron trifluoride diethyl etherate (see Kunz et al; *Hel. Chim Acta*; 68; 1985; 283-287), Tin(II) chloride (see O'Leary et al; *J. Org. Chem.*; 59; 1994; 6629-6636), alkoxide (see Shortnacy-Fowler et al; *Nucleosides Nucleotides*; 20; 2001; 1583-
30 1598), and iodine (see Kartha et al; *J. Chem. Soc. Perkins Trans. 1*; 2001; 770-772). These methods can be selectively used in conjunction with different methods in forming 518-1.5 with various leaving groups (LG) to produce 518-1.6.

The introduction and removal of protecting groups from a compound is a commonly practiced art in organic synthesis. Many sources of information of the art are available in the published literature, e.g. Greene and Wuts, *Protecting Groups in Organic Synthesis*, 3rd Ed., John Wiley & Sons, Inc., 1999. The main purpose is to temporarily transform a functional group so that it will survive a set of subsequent reaction procedures. Afterwards, the original functional group can be restored by a preconceived deprotection procedure. Therefore, the transformations from 518-1.1 to 518-1.2, from 518-1.2 to 518-1.3, and from 518-1.6 to 518-A are intended to allow the core components of the transformations (from 518-1.3 to 518-1.6) to occur while preserving the functional groups already exist in the compound structures.

The 5'-hydroxyl group of ribavirin (518-2) can be selectively protected by an appropriate protecting group. The product, 518-3, can be treated with benzoyl chloride, an appropriate base, in the presence of catalytic amount of 4-dimethylaminopyridine, to convert 2'- and 3'-hydroxyl groups to their corresponding benzoyl esters, 518-4. The 5'-hydroxyl group can be selectively deprotected to give 5. Following procedure described for analogous compound in US6,087,482, Figure 2, 518-4 can be converted to 518-7 in a three-step sequence. Treating 518-7 with a coupling agent, such as trimethylsilyl trifluoromethanesulfonate, in the presence of an appropriate alcohol containing a phosphonate group can produce 518-8. Lastly, treating 518-8 with aqueous sodium hydroxide can deprotect the 2'- and 3'-hydroxyl groups to give 518-1. It is important to point out that R^{P1} and R^{P2} in 518-8 and 518-1 do not need to be the same.

A variety of compounds of the general structure 518-1.1 can either be prepared using procedures described in the literature, or be purchased from commercial sources. The following are good sources for information on the art of preparing a variety of compounds of the general structure 518-1.1, Townsend, *Chemistry of Nucleosides and Nucleotides*, Plenum Press, 1994; and Vorbruggen and Ruh-Pohlenz, *Handbook of Nucleoside Synthesis*, John Wiley & Sons, Inc., 2001. Compound **518-2.1** in Scheme 518-2 is prepared using method described (WO 01/90121, page 115, table). The 5'-hydroxyl in **518-2.1** is protected as t-butylidimethylsilyl (TBDMS) ether. The 2'- and 3'- hydroxyl groups can be
 5 protected as benzoyl (Bz) esters to give **518-2.2**. The 5'-hydroxyl can then be deprotected to give **518-2.3**. Oxidation using iodobenzene diacetate and 2,2,6,6-tetramethyl-1-piperidinyloxy, free radical (TEMPO) convert the primary alcohol to the corresponding acid **518-2.4**. Further oxidation of **518-2.4** using lead
 10 tetraacetate can produce **518-2.5**. Coupling between **518-2.5** and diethyl hydroxymethylphosphonate (available from Sigma-Aldrich, Cat. No. 39,262-6) effected by TMS-OTf can afford **518-2.6**. Treating **518-2.6** with TMS-Br converts the phosphodiester to the corresponding phosphonic acid **518-2.7**. Deprotection of the 2'- and 3'- hydroxyl gives **518-2.8** as an example of the
 15 generic structure **518-A**, where Base is an adenine, R¹, R⁵, and R⁶ are hydrogen, R² is methyl group, R³ and R⁴ are hydroxyl groups, linker is a methylene group, and R^{P1} and R^{P2} are both hydroxyl groups.

Scheme 518-2

The phosphonic acids in 518-2.7 and 518-2.8 are used as examples for illustration purpose. Other forms of phosphonates can be access via the phosphonic acid, or other forms, such as the corresponding diesters. See section INTERCONVERSIONS OF PHOSPHONATES for details.

Many compounds of the generic structure 518-1.1 with the sugar moiety in its L-configuration are either commercially available or can be prepared by procedures described in the published literature. The opposite D-configuration enantiomers of the L-nucleoside analogs previously discussed can be prepared from the precursors that are the opposite enantiomers of 518-3.1, 518-3.2, and 518-3.3. Scheme 518-3 describes the preparation of the opposite enantiomers of 518-3.1, 518-3.2, and 518-3.3.

15 Scheme 518-3

The commercially available starting material 518-4.1 can be converted to 518-4.4, which is the opposite enantiomer of 518-3.1, using the sequence of reactions outlined above in Scheme 518-3. The osmium tetroxide catalyzed dihydroxylation reaction should introduce the diol selectively in the opposite face to the tert-butyldimethylsilyl (TBDMS) ether of the hydroxymethyl group. The diol in intermediate 518-4.3 can be protected as TBDMS ether. Diisobutylaluminum hydride reduction of the lactone at low temperature should produce 518-4.6, which can be converted to 518-4.6 by acetylation. Deprotection of 518-4.6 should produce L-ribose (518-4.7). Acylation reaction can convert all hydroxyl groups in 518-4.7 to the corresponding benzoyl esters. Standard coupling reactions with a variety of nucleobases should produce 518-4.10, which is the opposite enantiomer of 518-3.3.

Scheme 518-4

The synthesis of 3-cyano-1-(2,3,5-tri-O-acetyl-β-D-ribofuranosyl)-1,2,4-triazole (518-2) is described in US 2002/0156030 A1, page 6, paragraph 0078 to paragraph 0079. Using this starting material, one can synthesize carboxamide compound 518-1 (Scheme 518-4) or formamidine compound 518-1 (Scheme 518-5) using the sequences of chemical transformations outlined in Schemes 518-4 and 518-5, respectively.

Scheme 518-5

- 5 Appropriate protection, deprotection procedures (See Greene and Wuts, (1999) *Protective Groups in Organic Synthesis*,) can be employed to prepare 518-3, in which the 5'-hydroxyl group is protected, while the 2', and 3'-hydroxyl groups are not (Schemes 518-4 and 518-5). Subsequent protection, deprotection procedures can introduce protecting groups such as benzoyl group to the 2'- and
- 10 3'-hydroxyl, and leave the 5'-hydroxyl group unprotected as in 518-4. Oxidation can convert the primary alcohol in 518-4 to the corresponding carboxylic acid or its ester. An optional deprotection of the ester can give the acid 518-5 as product. Further oxidation using oxidant such as lead tetraacetate can convert 518-5 to 518-6, in which the leaving group is an acetate. Treating
- 15 518-6 with an alcohol containing a phosphonate moiety in the presence of appropriate coupling agent, such as trimethylsilyl trifluoromethanesulfonate, will give 518-8 as product. Finally, treating 518-8 with the procedure described in US 2002/0156030 A1, page 6, paragraph 0081, should give 518-1 as product. It is important to point out that R^{P1} and R^{P2} in 518-7, 518-8 and 518-1 do not need
- 20 to be the same.

The conversion from **518-27** to **518-28** is described in Scheme 518-2 above. The conversion of **518-28** to the corresponding diphosphosphonate **518-29** and phosphorus prodrugs, e.g. **518-30** can be accomplished using procedures described herein.

Cyclopentyl intermediate **518-31** may be prepared by procedures analogous to those described in US5206244 and US5340816 (Scheme 518-4).  methylenation using the procedure of Nysted (US3865848; *Aldrichim. Acta*

 10 sodium methoxide and the resulting alcohol is inverted by the Mitsunobo
 protocol, and a second acetate deprotection produces 518-44. Desilylation with
 tetra-butylammonium fluoride (TBAF) of 518-44 will yield 518-45.

Example 257 Synthesis of Exemplary Compounds of the Invention

The following Schemes 555-5 to 555-9 describes a general method of preparing the [3.1.0] bicyclo hexane scaffold of the Formula 555-I and 555-II compounds. Exemplary structures, intermediates, substituents, protecting groups, reagents, and synthetic routes chosen for description here are meant to merely illustrate general methods of preparation, and are not intended to any way limit or denote preference to the methods.

The [3.1.0] bicyclo hexane scaffold may be synthesized by intramolecular cyclopropanation of a carbene generated by decomposition of a diazo 1,3-ketoester (Moon et al (2000) *Organic Letters* 2(24):3793-3796). The requisite 1,3-ketoester 555-5.1 may be prepared from acetoacetate ester anion addition to ene-aldehydes, e.g. acrolein (Scheme 555-5a). For example, ethyl acetoacetate treated with 2 equivalents of lithium diisopropylamide at -78 °C and then one equivalent of acrolein gives the 1,3-ketoester 555-5.1 (Yoshimura et al (2002) *Jour. Org. Chem.* 67:5938-5945). Protection of the hydroxyl may be accomplished with phenyldimethylsilyl chloride to give 555-5.2 where PG is phenyldimethylsilyl (PhMe₂Si-). Other trialkylsilyl protecting groups may be useful. Diazotization of 2 with p-toluenesulfonyl azide gives 555-5.3. Treatment of 555-5.3 with a carbenoid insertion catalyst, e.g. CuSO₄ or Rh(OAc)₂, gives 555-5.4 as a mixture of diastereomers.

Scheme 555-5a

The ester of 555-5.4 may be hydrolyzed to the hydroxymethyl 555-5.5 or saponified directly to carboxylic acid 555-5.6 (Scheme 555-5b). Appropriate oxidant(s) can convert the primary alcohol 555-5.5 to carboxylic acid 555-5.6 or its corresponding ester. In the case of an ester, an additional deprotection step will give the carboxylic acid, 555-5.6. A variety of oxidation procedures exist in the literature and can be utilized here. These include but are not limited to the following methods: (i) pyridinium dichromate in Ac₂O, t-BuOH, and dichloromethane producing the t-butyl ester, followed by a deprotection using reagent such as trifluoroacetic acid to convert the ester to the corresponding carboxylic acid (see Classon, et al, *Acta Chem. Scand. Ser. B*; 39; 1985; 501-504. Cristalli, et al; *J. Med. Chem.*; 31; 1988; 1179-1183.); (ii) iodobenzene diacetate and 2,2,6,6-tetramethyl-1-piperidinyloxy, free radical (TEMPO) in acetonitrile, producing the carboxylic acid (See Epp, et al; *J. Org. Chem.* 64; 1999; 293-295. Jung et al; *J. Org. Chem.*; 66; 2001; 2624-2635.); (iii) sodium periodate, ruthenium(III) chloride in chloroform producing the carboxylic acid (see Kim, et al, *J Med. Chem.* 37; 1994; 4020-4030. Homma, et al; *J. Med. Chem.*; 35; 1992; 2881-2890); (iv) chromium trioxide in acetic acid producing the carboxylic acid (see Olsson et al; *J. Med. Chem.*; 29; 1986; 1683-1689. Gallo-Rodriguez et al; *J. Med. Chem.*; 37; 1994; 636-646); (v) potassium permanganate in aqueous potassium hydroxide producing the carboxylic acid (see Ha, et al; *J. Med. Chem.*; 29; 1986; 1683-1689. Franchetti, et al; *J. Med. Chem.*; 41; 1998; 1708-1715.) (vi) nucleoside oxidase from *S. maltophilia* to give the carboxylic acid (see Mahmoudian, et al; *Tetrahedron*; 54; 1998; 8171-8182.)

Carboxylic acid 555-5.6 may be converted by decarboxylation to acetate 555-5.7 using lead(IV) tetraacetate (Teng et al; (1994) *J. Org. Chem.*; 59:278-280; Schultz, et al; *J. Org. Chem.*; 48; 1983; 3408-3412. When lead(IV) tetraacetate is used together with lithium chloride (see Kochi, et al; *J. Am. Chem. Soc.*; 87; 1965; 2052), the corresponding chloride is obtained 555-5.8. Lead(IV) tetraacetate in combination with N-chlorosuccinimide can also produce 555-5.8 (Wang, et al; *Tet. Asym.*; 1; 1990; 527 and Wilson et al; *Tet. Asym.*; 1; 1990; 525). Alternatively, the acetate can also be converted to other leaving groups

such as bromide by treatment of trimethylsilyl bromide (Spencer, et al; *J. Org. Chem.*; 64; 1999; 3987-3995).

5 Scheme 555-5b

Intermediates 555-5.7 and 555-5.8 may react with a variety of nucleophiles as described by Teng et al; *Synlett*; 1996; 346-348 and US 6087482; Column 54 line 64 to Column 55 line 20. Specifically, 555-5.7 may be reacted with diethyl hydroxymethylphosphonate in the presence of trimethylsilyl trifluoromethanesulfonate (TMS-OTf) to give 555-5.9 (Scheme 555-5c). It can be envisioned that other compounds with the general structure of HO-linker-POR^{P1}R^{P2} can also be used so long as the functional groups in these compounds are compatible with the coupling reaction conditions. There are many examples in the published literature describing the coupling of 1' acetyl furanosyl compounds with a variety of alcohols. The reactions can be facilitated with a number of reagents, such as silver(I) salts (see Kim et al (1991) *J. Org. Chem.* 56:2642-2647, Toikka et al (1999) *J. Chem. Soc. Perkins Trans. 1*; 13:1877-1884); mercury(II) salts (see Veeneman et al (1987) *Recl. Trav. Chim. Pays-Bas*; 106:129-131); boron trifluoride diethyl etherate (see Kunz et al (1985) *Hel. Chim Acta*; 68:283-287); tin(II) chloride (see O'Leary et al (1994) *J. Org. Chem.* 59:6629-6636); alkoxide (see Shortnacy-Fowler et al (2001) *Nucleosides & Nucleotides*; 20:1583-1598); and iodine (see Kartha et al (2001) *J. Chem. Soc. Perkins Trans. 1* 770-772). These methods can be selectively used in conjunction with different methods in forming intermediates from 555-5.6 with various leaving groups (LG).

Scheme 555-5c

The introduction and removal of protecting groups (represented in the structures herein as PG) from a compound is common practice art in organic synthesis. Many sources of information of the art are available in the published literature, e.g. Greene and Wuts, *Protecting Groups in Organic Synthesis*, 3rd Ed., John Wiley & Sons, Inc., 1999. The main purpose is to temporarily transform a functional group and mask its reactivity so that it will survive a set of subsequent reaction procedures. Afterwards, the original functional group can be restored by a preconceived deprotection procedure. Therefore, the transformations in Schemes 555-(5a-c) are intended to build the [3.1.0] scaffold with the appropriate latent functionality or reactivity components.

The keto group of certain intermediates, e.g. 555-5.4 may be elaborated to ribofuranose-type analogs 555-6.1 where Z¹ are for example, each hydroxyl or protected hydroxyl (Scheme 555-6). The hydroxyl groups can be protected as benzoyl (Bz) esters to give 555-6.2. The bridgehead carboxylate ester can then be orthogonally hydrolyzed to give 555-6.3 or reduced to hydroxymethyl 555-6.4. Oxidation of 555-6.4, e.g. using iodobenzene diacetate and 2,2,6,6-tetramethyl-1-piperidinyloxy, free radical (TEMPO), converts the primary alcohol to the corresponding acid 555-6.3. Further oxidation of 555-6.3 using lead tetraacetate can produce acetate 555-6.5. Coupling between 555-6.5 and hydroxyalkyl dialkylphosphonate compounds, e.g. diethyl hydroxymethylphosphonate (available from Sigma-Aldrich, Cat. No. 39,262-6) and TMS-OTf can afford 555-6.6. Treating 555-6.6 with TMS-Br converts the phosphodiester to the corresponding phosphonic acid 555-6.7. Deprotection, e.g. NH₃ in methanol, of the 2'- and 3'- hydroxyl gives 555-6.8.

**Scheme 555-6**

The phosphonic acids in 555-(6.6-6.8) are used as examples for illustration purpose. Other forms of phosphonates can be accessed via the phosphonic acid, or other forms, such as the corresponding diesters. See Schemes 555-A and 555-(1-4) for exemplary interconversions of phosphonate moieties.

Compounds such as 555-6.6 can be further elaborated by selective deprotection of PG and introduction of the nucleobase moiety (B). For example, where PG is trialkylsilyl, e.g. triethylsilyl, t-butyldimethylsilyl, or phenyldimethylsilyl, treatment of 555-6.6 with a fluoride reagent, e.g. tetrabutylammonium fluoride in THF, may selectively remove PG. The resulting hydroxyl may be converted to a leaving group (LG) such as chloro or acetate 555-7.1 under Vorbruggen-type reaction conditions, or the hydroxyl 555-7.2 reacted *in situ*, e.g. Mitsunobu conditions, to establish the carbon-nitrogen

bond with a nucleobase or protected nucleobase reagent to give 555-7.3 (Scheme 555-7). Suitable nucleobase or protected nucleobase reagents (B) include thymidine, cytosine, adenine, guanine, and silylated forms thereof. The resulting covalent attachment may be 9-purinyl or 1-pyrimidinyl. Other positional isomers may result and conventional means of separation may be employed to generate pure 555-7.3 compounds. The 2' and 3' protecting groups (Bz = benzoyl) may be removed from intermediate 555-7.3 with aqueous base to give 555-7.4. The ethyl groups of 555-7.4 may be removed with a dealkylation reagent such as trimethylsilyl bromide to give phosphonic acid 555-7.5 which may be further elaborated according to the reactions shown in Schemes 555-A and 1-4 to other phosphonate moieties, including diphosphosphonate and phosphosphonate compounds.

Scheme 555-7

15 Scheme 555-8 shows an exemplary route to 2'-β-methyl, 2'-3' hydroxyl bicyclo adenine compounds. The 3' and 5' hydroxyl groups of [3.1.0] bicyclo

- analog of adenosine **555-8.1** (Kim, et al (2002) J. Med. Chem. 45:208-218) may be selectively silylated to give **555-8.2**. The 2' hydroxyl group may be oxidized under Dess-Martin periodinane conditions to give **555-8.3**. The 2' keto of **555-8.3** may be methylenated with a Wittig reagent and desilylated to give **555-8.4**.
- 5 Epoxidation of **555-8.4** gives **555-8.5**. Hydride attack on the methylene carbon of the epoxide **555-8.5** gives **555-8.6** with the 2',3'- α -dihydroxy, 2'- β -methyl motif. This synthetic route may be versatile in the preparation of a variety of 2',3'- α -dihydroxy, 2'- β -methyl[3.1.0] bicyclo compounds where B = any protected or unprotected nucleobase.

Scheme 555-8

- The 5' hydroxymethyl group of 2',3'- α -dihydroxy, 2'- β -methyl [3.1.0] bicyclo compounds, e.g. **555-8.6**, may be elaborated by selective reactions such as those shown in Scheme 555-9. The 5' carbon may be removed by an
- 15 oxidative decarboxylation to allow attachment of a phosphonate moiety through an oxygen atom bound directly to the [3.1.0] scaffold. The 5' hydroxyl group of **555-8.6** may be selectively protected as the 5' *tert*-butyldiphenylsilyl ether (TBDPS) and then the 2' and 3' hydroxyls may be protected as methoxymethyl ethers to give **555-9.1**. The 5' TBDPSi group may be removed with tetra-butyl

ammonium fluoride (TBAF) and the resulting hydroxymethyl oxidized with the periodinane reagent, $\text{PhI}(\text{OAc})_2$ and TEMPO to the carboxylic acid **555-9.2**. Oxidative decarboxylation of **555-9.2** with lead tetracetate and treatment with lithium hydroxide gives **555-9.3**. Alkylation of the hydroxyl of **555-9.3** with bromomethyldiethyl phosphonate gives **555-9.4**. The phosphonate ethyl groups and the 2',3' methoxymethyl (MOM) protecting groups may be removed with iodotrimethylsilane to give **555-9.5**. The phosphonic acid group of **555-9.5** may be activated, for example with carbonyldiimidazole (CDI) and reacted with pyrophosphate anion to give diphosphophosphonate **555-9.6**. Other phosphonic acid conversions may be conducted, as described in Schemes 555-A and 555(1-4).

Scheme 555-9

Intermediate **555-8.2** is versatile for the preparation of 2' hydroxyl [3.1.0] bicyclo compounds (Scheme 555-10). Protection of the 2' hydroxyl with para-methoxybenzyl bromide and silyl removal with TBAF gives **555-10.1**. The 5' hydroxyl is protected with the TBDPSi group to give **555-10.2**. The 3' thioester of **555-10.2** is formed with phenyl chlorothionoformate followed by reduction with tributyl tin hydride with AIBN to give **555-10.3**. Desilylation with TBAF and oxidation with BAIB and TEMPO furnishes the carboxylic acid **555-10.4**.

10 Scheme 555-10

Oxidative decarboxylation of **555-10.4** with lead tetracetate followed by lithium hydroxide treatment gives the hydroxyl **555-11.1** (Scheme 555-11). Alkylation of hydroxyl **555-11.1** with bromomethyl diethyl phosphonate gives **555-11.2**. Iodotrimethylsilane cleaves the ethyl groups from the diethylphosphonate and ceric ammonium nitrate deprotects the para-methoxy benzyl group of **555-11.2** to give **555-11.3**. Phosphonate activation with CDI and addition of pyrophosphate gives the 2'-hydroxy diphosphophosphonate [3.1.0] compound **555-11.4**.

Schemes 556 (A-F) show the synthetic routes which have been utilized to prepare the exemplary embodiments shown therein.

Scheme 556-A

- The (-) enantiomer of adenosine 556-A.1 was tritylated at the N-6 of the adenine exocyclic amine and the 5' hydroxyl with an excess of trityl (Tr, triphenylmethyl, $\text{Ph}_3\text{C-}$) chloride with dimethylaminopyridine in pyridine to give bis-trityl 556-A.2 which was treated with triflic anhydride in dichloromethane and DMAP to give 556-A.3 (Scheme 556-A). The 2' triflate group was displaced by fluoride with tetra-butylammonium fluoride in THF at room temperature to give 556-A.4.

Example 259

By way of example and not limitation, embodiments of the invention are named below in tabular format (Table 100). These embodiments are of the general formula "MBF":

MBF

5

Each embodiment of MBF is depicted as a substituted nucleus (Sc). Sc is described in formula 1-108 herein, wherein A⁰ is the point of covalent attachment of Sc to Lg, as well as in Tables 1.1 to 1.5 below. For those

10 embodiments described in Table 100, Sc is a nucleus designated by a number and each substituent is designated in order by letter or number. Tables 1.1 to 1.5 are a schedule of nuclei used in forming the embodiments of Table 100. Each nucleus (Sc) is given a number designation from Tables 1.1 to 1.5, and this designation appears first in each embodiment name. Similarly, Tables 10.1 to

15 10.19 and 20.1 to 20.36 list the selected linking groups (Lg) and prodrug (Pd¹ and Pd²) substituents, again by letter or number designation, respectively. Accordingly, a compound of the formula MBF includes compounds having Sc groups based on formula 1-108 herein as well as compounds according to Table 100 below. In all cases, compounds of the formula MBF have groups Lg, Pd¹

20 and Pd² setforth in the Tables below.

Accordingly, each named embodiment of Table 100 is depicted by a number designating the nucleus from Table 1.1-1.5, followed by a letter designating the linking group (Lg) from Table 10.1-10.19, and two numbers designating the two prodrug groups (Pd¹ and Pd²) from Table 20.1-20.36. In

25 graphical tabular form, each embodiment of Table 100 appears as a name having the syntax:

Each Sc group is shown having a tilda ("~"). The tilda is the point of covalent attachment of Sc to Lg. Q¹ and Q² of the linking groups (Lg), it should be understood, do not represent groups or atoms but are simply connectivity designations. Q¹ is the site of the covalent bond to the nucleus (Sc) and Q² is the site of the covalent bond to the phosphorous atom of formula MBF. Each prodrug group (Pd¹ and Pd²) are covalently bonded to the phosphorous atom of MBF at the tilda symbol ("~"). Some embodiments of Tables 10.1-10.19 and 20.1-20.36 may be designated as a combination of letters and numbers (Table 10.1-10.19) or number and letter (Table 20.1-20.36). For example there are Table 10 entries for BJ1 and BJ2. In any event, entries of Table 10.1-10.19 always begin with a letter and those of Table 20.1-20.36 always begin with a number. When a nucleus (Sc) is shown enclosed within square brackets ("[]") and a covalent bond extends outside the brackets, the point of covalent attachment of Sc to Lg may be at any substitutable site on SC. Selection of the point of attachment is described herein. By way of example and not limitation, the point of attachment is selected from those depicted in the schemes and examples.
